## ON THE ASYMPTOTIC BEHAVIOR OF SOME COUNTING FUNCTIONS

BY<br>MACIEJ RADZIEJEWSKI (Poznań) and WOLFGANG A. SCHMID (Graz)

#### Abstract

The investigation of certain counting functions of elements with given factorization properties in the ring of integers of an algebraic number field gives rise to combinatorial problems in the class group. In this paper a constant arising from the investigation of the number of algebraic integers with factorizations of at most $k$ different lengths is investigated. It is shown that this constant is positive if $k$ is greater than 1 and that it is also positive if $k$ equals 1 and the class group satisfies some additional conditions. These results imply that the corresponding counting function oscillates about its main term. Moreover, some new results on half-factorial sets are obtained.

1. Introduction. We study a combinatorial problem arising from the investigation of factorizations of distinct lengths in algebraic number fields and in some more general settings. Let $K$ be an algebraic number field, $\mathcal{O}_{K}$ its ring of integers and $G$ its ideal class group. If $a \in \mathcal{O}_{K}$ and $a=u_{1} \cdots u_{n}$ is a factorization of $a$ into atoms (irreducibles), then $n$ is called the length of the factorization and $\mathrm{L}(a)=\{n \mid a$ has a factorization of length $n\}$ is called the set of lengths of $a$.

Let $k$ be a positive integer and $|G| \geq 3$. Then $\mathbf{G}_{k}=\{(a)| | \mathrm{L}(a) \mid \leq k\}$ denotes the set of principal ideals generated by elements with factorizations of at most $k$ different lengths and

$$
\mathbf{G}_{k}(x)=\mid\{(a) \mid N(a) \leq x \text { and }|\mathrm{L}(a)| \leq k\} \mid
$$

the associated counting function. It is known (cf. [5]) that

$$
\mathbf{G}_{k}(x) \sim C x(\log x)^{-1+\mu(G) /|G|}(\log \log x)^{\psi_{k}(G)}
$$

for a $C>0$ and non-negative integers $\mu(G)$ and $\psi_{k}(G)$ that depend on $G$ (respectively $G$ and $k$ ) alone. The invariants $\mu(G)$ and $\psi_{k}(G)$ are defined in combinatorial terms for any finite abelian group $G$ (cf. Section 2 for the

[^0]definitions). They remain meaningful in the more general case of arithmetical Krull monoids or formations (cf. [12]). There is considerable literature on $\mu(G)$ (cf. Section 5), but little is known about $\psi_{k}(G)$.

The aim of this paper is to show the positivity of $\psi_{k}(G)$ for various $G$ and $k$. The study of this specific problem is motivated by analytic investigations of $\mathbf{G}_{k}(x)$ in [20]. There it was shown that $\psi_{k}(G)>0$ implies the existence of oscillations of $\mathbf{G}_{k}(x)$ about its main term (cf. Section 3 for a detailed discussion).

We demonstrate that $\psi_{k}(G)>0$ for all $k \geq 2$ and $G$ with at least three elements (Theorem 6.1). For $k=1$ we are able to prove the positivity for various types of groups (Section 7). Moreover, we will obtain some results on half-factorial sets (Propositions 5.2 and 5.4).

The investigation of the function $\mathbf{G}_{k}(x)$ was started by W. Narkiewicz (cf. $[15,16,17,19])$ who also stated the problem of evaluating $\mu(G)$ (cf. [18, P 1142]). J. Śliwa (cf. [24, 25]) considered the counting functions associated to the sets $\overline{\mathbf{G}}_{k}=\mathbf{G}_{k} \backslash \mathbf{G}_{k-1}$ and demonstrated that

$$
\overline{\mathbf{G}}_{k}(x) \sim C^{\prime} x(\log x)^{-A(k, G)}(\log \log x)^{B(k, G)}
$$

for some positive $C^{\prime}=C^{\prime}(k, K)$ and $A(k, G)$, and non-negative $B(k, G)$. Note that $\overline{\mathbf{G}}_{1}=\mathbf{G}_{1}$. J. Śliwa determined $B(k, G)$ for $|G| \leq 4$ and conjectured (cf. [25, P 1247]) that $A(k, G)=1-\mu(G) /|G|$ for all $k$ and $(B(k, G))_{k=1}^{\infty}$ is an arithmetic progression. A. Geroldinger (cf. [5]) showed that $A(k, G)=$ $1-\mu(G) /|G|$ for infinitely many $k$. It is relatively straightforward to see that

$$
\psi_{k}(G)=\max _{l \leq k, A(l, G)=1-\mu(G) /|G|} B(l, G)
$$

Thus the conjecture of J. Śliwa is equivalent to the statement that $\left(\psi_{k}(G)\right)_{k=1}^{\infty}$ is an arithmetic progression. In general it is only known that $0 \leq \psi_{1}(G)$ $\leq \psi_{2}(G) \leq \cdots$ and $\lim _{k \rightarrow \infty} \psi_{k}(G)=\infty$. See also J. Kaczorowski [13] for better asymptotic estimates of $\mathbf{G}_{k}(x)$, and F. Halter-Koch [10], A. Geroldinger and J. Kaczorowski [8], and A. Geroldinger, F. Halter-Koch and J. Kaczorowski [7] for investigations of the analogues of the sets $\mathbf{G}_{k}$ in more general settings.

The first author would like to thank the Karl-Franzens-Universität for support and excellent working conditions during his visit to Graz.
2. Preliminaries. Let $\mathbb{N}$ denote the set of positive integers, $\mathbb{N}_{0}$ the non-negative integers and $\mathbb{P}$ the prime numbers. For $n \in \mathbb{N}$ let $C_{n}$ denote a cyclic group with $n$ elements. Throughout the paper, $G$ will denote an additively written, finite abelian group.

For $G_{0} \subset G$ we denote by $\left\langle G_{0}\right\rangle \subset G$ the subgroup generated by $G_{0}$ and we call $G_{0}$ a generating set if $\left\langle G_{0}\right\rangle=G$. A subset $\left\{e_{1}, \ldots, e_{r}\right\} \subset G \backslash\{0\}$ is called (or its elements are called) independent if $\sum_{i=1}^{r} m_{i} e_{i}=0$ with $m_{i} \in \mathbb{Z}$ implies $m_{i} e_{i}=0$ for each $i \in\{1, \ldots, r\}$. An independent generating subset of $G$ is called a basis. By $r(G)$ we denote the $\operatorname{rank}$ and by $\exp (G)$ the exponent of $G$.

We recall the definition of block monoids and several related notions; for a detailed description we refer to the survey articles [2, 11] in [1]. For a subset $G_{0} \subset G$ we denote by $\mathcal{F}\left(G_{0}\right)$ the multiplicatively written, free abelian monoid with basis $G_{0}$. An element $S=\prod_{i=1}^{l} g_{i} \in \mathcal{F}\left(G_{0}\right)$ with $l \in \mathbb{N}_{0}$ and $g_{i} \in G_{0}$ is called a sequence in $G_{0}$ and has a unique representation $S=\prod_{g \in G} g^{\mathrm{v}_{g}(S)}$ with $\mathrm{v}_{g}(S) \in \mathbb{N}_{0}$. By $1 \in \mathcal{F}\left(G_{0}\right)$ we denote the empty sequence, i.e., the identity element of $\mathcal{F}\left(G_{0}\right)$. If $T \mid S$ (in $\mathcal{F}\left(G_{0}\right)$ ), then we call $T$ a subsequence of $S$ and we denote by $T^{-1} S$ its co-divisor. We denote by $|S|=l$ the length, by $\mathrm{k}(S)=\sum_{i=1}^{l} 1 / \operatorname{ord}\left(g_{i}\right)$ the cross number and by $\sigma(S)=\sum_{i=1}^{l} g_{i}$ the sum of $S$. Further $\mathrm{K}(G)=\max \{\mathrm{k}(A) \mid A \in \mathcal{A}(G)\}$ denotes the cross number of $G$. Note that $\sigma(S)$ is used to denote the length of the sequence in several of the articles we cite. The length, cross number and sum define monoid homomorphisms from $\mathcal{F}\left(G_{0}\right)$ to $\left(\mathbb{N}_{0},+\right),(\mathbb{Q} \geq 0,+)$ and $G$, respectively.

A sequence $S \in \mathcal{F}\left(G_{0}\right)$ is called a zero-sum sequence (a block) if $\sigma(S)=0$, and it is called zero-sumfree if $\sigma(T) \neq 0$ for every $1 \neq T \mid S$. The set of all blocks, $\mathcal{B}\left(G_{0}\right)$, is called the block monoid over $G_{0}$. It is a Krull monoid and its atoms, $\mathcal{A}\left(G_{0}\right)$, are the minimal zero-sum sequences, i.e., zero-sum sequences such that no proper subsequence has sum zero. Let $B \in \mathcal{B}\left(G_{0}\right)$ and let $B=\prod_{i=1}^{n} U_{i}$ with $U_{i} \in \mathcal{A}\left(G_{0}\right)$ be a factorization of $B$ into atoms. Then we call $n$ the length of the factorization. The set $\mathrm{L}(B)=$ $\{n \mid B$ has a factorization of length $n\}$ is called the set of lengths of $B$ and is a finite subset of $\mathbb{N}_{0}$ (for $B=1$ we have $\mathrm{L}(B)=\{0\}$ ). For $k \in \mathbb{N}_{0}$ we set $\mathcal{G}_{k}(G)=\{B \in \mathcal{B}(G)| | \mathrm{L}(B) \mid \leq k\}$. Note that $\mathcal{G}_{0}(G)=\emptyset$.

A subset $G_{0} \subset G$ is called half-factorial if $\mathcal{B}\left(G_{0}\right)$ is a half-factorial monoid, i.e., $|\mathrm{L}(B)|=1$ for every $B \in \mathcal{B}\left(G_{0}\right)$. Let

$$
\mu(G)=\max \left\{\left|G_{0}\right| \mid G_{0} \subset G \text { half-factorial }\right\}
$$

denote the maximal cardinality of a half-factorial subset of $G$, an invariant introduced in [24]. The main tool for investigations on half-factorial sets is the following characterization (cf. $[23,24,26]$ and for example [2, Proposition 5.4]): A set $G_{0} \subset G$ is half-factorial if and only if $\mathrm{k}(A)=1$ for each $A \in$ $\mathcal{A}\left(G_{0}\right)$. In Section 5 we provide several further results on half-factorial sets, which we will need in Section 7 . A subset $G_{0} \subset G$ is said to satisfy condition $\left(C_{0}\right)$ if $\mathrm{k}(A) \in \mathbb{N}$ for each $A \in \mathcal{A}\left(G_{0}\right)$ (cf. [25] and [3, Section 4]).

Let $G_{0} \subset G$ and $S \in \mathcal{F}\left(G \backslash G_{0}\right)$. Then

$$
\begin{aligned}
\Omega\left(G_{0}, S\right) & =S \mathcal{F}\left(G_{0}\right) \cap \mathcal{B}(G) \\
& =\left\{B \in \mathcal{B}(G) \mid \mathrm{v}_{g}(B)=\mathrm{v}_{g}(S) \text { for each } g \in G \backslash G_{0}\right\}
\end{aligned}
$$

Having these notations we are ready to recall the central definition of this paper (cf. [5]).

Definition 2.1. Let $G$ be a finite abelian group with at least three elements and let $k \in \mathbb{N}$. Then

$$
\begin{array}{r}
\psi_{k}(G)=\max \left\{|S| \mid G_{0} \subset G \text { half-factorial with }\left|G_{0}\right|=\mu(G)\right. \text { and } \\
\\
\left.S \in \mathcal{F}\left(G \backslash G_{0}\right) \text { with } \emptyset \neq \Omega\left(G_{0}, S\right) \subset \mathcal{G}_{k}(G)\right\}
\end{array}
$$

3. The counting function $\mathbf{G}_{k}(x)$. In this section we state the main arithmetical results of this paper. We say that a real, piecewise continuous function $f(x)$ is subject to oscillations of lower logarithmic frequency $\gamma$ and size $x^{\theta-\varepsilon}$ (for $\gamma>0, \theta$ real) if there exists an increasing sequence $\left(x_{n}\right)_{n=1}^{\infty}$ of positive real numbers with $\lim _{n \rightarrow \infty} x_{n}=\infty$ such that:
(1) $f\left(x_{n}\right) \neq 0$ for each $n$ and the signs of $f\left(x_{n}\right)$ alternate.
(2) If $V(Y)$ denotes the number of terms of $\left(x_{n}\right)$ not exceeding $Y$, then

$$
\liminf _{Y \rightarrow \infty} \frac{V(Y)}{\log Y}=\gamma
$$

(3) If $\varepsilon>0$, then for any $Y$ sufficiently large the segment $\left[Y^{1-\varepsilon}, Y\right]$ contains at least one element of $\left(x_{n}\right)$.
(4) We have

$$
\liminf _{n \rightarrow \infty} \frac{\left|f\left(x_{n}\right)\right|}{x_{n}^{\theta-\varepsilon}}=\infty
$$

for every $\varepsilon>0$.
The function

$$
\mathbf{M}_{k}(x)=\frac{1}{2 \pi i} \int_{\mathcal{C}} \zeta\left(s, \mathbf{G}_{k}\right) \frac{x^{s}}{s} d s, \quad x \geq 1
$$

where $\mathcal{C}$ is a contour starting at $1 / 2-\delta$, for a small $\delta>0$, going closely around $[1 / 2,1]$, counterclockwise, and back to $1 / 2-\delta$, and $\zeta\left(s, \mathbf{G}_{k}\right)$ is defined by

$$
\zeta\left(s, \mathbf{G}_{k}\right)=\sum_{\mathfrak{a} \in \mathbf{G}_{k}} \frac{1}{\mathrm{~N}(\mathfrak{a})^{s}}
$$

for $\operatorname{Re} s>1$ and by analytic continuation in a larger area, is called the main term of $\mathbf{G}_{k}(x)$ (cf. [13], [14, Theorem 3] and [20]), and the difference is called the error term. For $x<1$ we set $\mathbf{M}_{k}(x)=0$. In [20] it was proved that the positivity of $\psi_{k}(G)>0$ implies the existence of oscillations of $\mathbf{G}_{k}(x)-\mathbf{M}_{k}(x)$.

Theorem 3.1 ([20]). Let $K$ be an algebraic number field with ideal class group $G$ and let $k$ be a positive integer. If $|G| \geq 3$ and $\psi_{k}(G)>0$, then the error term $\mathbf{G}_{k}(x)-\mathbf{M}_{k}(x)$ is subject to oscillations of positive lower logarithmic frequency and size $x^{1 / 2-\varepsilon}$.

Theorem 3.1 together with Theorem 6.1 now implies:
Theorem 3.2. Let $K$ be an algebraic number field with ideal class group $G$ and let $k \geq 2$ be a positive integer. If $|G| \geq 3$, then the error term $\mathbf{G}_{k}(x)-$ $\mathbf{M}_{k}(x)$ is subject to oscillations of positive lower logarithmic frequency and size $x^{1 / 2-\varepsilon}$.

More precise results can be obtained for quadratic number fields.
Proposition 3.3 ([21]). Let $K$ be a quadratic number field with ideal class group $G,|G| \geq 3$, and let $k$ be a positive integer. If $\psi_{k}(G)>0$ or there exists a half-factorial set $G_{0} \subset G$ with $\left|G_{0}\right|=\mu(G)$ containing an element $g \in G_{0}$ of order other than $1,2,3,4,6$, then the error $\operatorname{term} \mathbf{G}_{k}(x)-\mathbf{M}_{k}(x)$ is subject to oscillations of positive lower logarithmic frequency and size $x^{1 / 2-\varepsilon}$.

In this case using our Proposition $7.2(2)$ we obtain:
Corollary 3.4. Let $K$ be a quadratic number field with ideal class group $G,|G| \geq 3$, and suppose $G$ is not isomorphic to $C_{2}^{r} \oplus C_{4}^{s} \oplus C_{3}^{t}$ for any nonnegative integers $r, s, t \in \mathbb{N}$. Then the error term $\mathbf{G}_{1}(x)-\mathbf{M}_{1}(x)$ is subject to oscillations of positive lower logarithmic frequency and size $x^{1 / 2-\varepsilon}$.

Therefore the problem of oscillations of $\mathbf{G}_{1}(x)-\mathbf{M}_{1}(x)$ for quadratic fields is reduced to the study of $\psi_{1}(G)$ for some special types of groups. We further rule out some of the remaining cases in Theorem 7.1.
4. Auxiliary results. In this section we prove several results that are needed in Sections 6 and 7. Parts of the results of this section have already occurred (implicitly) in other articles (cf. [8, 24]).

Lemma 4.1. Let $\emptyset \neq G_{0} \subset G$ and $S, S^{\prime} \in \mathcal{F}\left(G \backslash G_{0}\right)$.
(1) $\Omega\left(G_{0}, S\right) \neq \emptyset$ if and only if $\sigma(S) \in\left\langle G_{0}\right\rangle$.
(2) $\Omega\left(G_{0}, S\right) \cdot \Omega\left(G_{0}, S^{\prime}\right) \subset \Omega\left(G_{0}, S S^{\prime}\right)$.
(3) Let $k, l \in \mathbb{N}_{0}$ be such that $\Omega\left(G_{0}, S\right) \not \subset \mathcal{G}_{k}(G)$ and $\Omega\left(G_{0}, S^{\prime}\right) \not \subset \mathcal{G}_{l}(G)$. Then

$$
\Omega\left(G_{0}, S S^{\prime}\right) \not \subset \mathcal{G}_{k+l}(G)
$$

(4) If $S \mid S^{\prime}$ and $\emptyset \neq \Omega\left(G_{0}, S^{\prime}\right) \subset \mathcal{G}_{k}(G)$ for some $k \in \mathbb{N}_{0}$, then $\Omega\left(G_{0}, S\right)$ $\subset \mathcal{G}_{k}(G)$.

Proof. (1) and (2) follow immediately from the definition.
(3) Let $B \in \Omega\left(G_{0}, S\right)$ with $|\mathrm{L}(B)| \geq k+1$, and $B^{\prime} \in \Omega\left(G_{0}, S^{\prime}\right)$ with $\left|\mathrm{L}\left(B^{\prime}\right)\right| \geq l+1$. The assertion follows from the inequalities

$$
\left|\mathrm{L}\left(B B^{\prime}\right)\right| \geq\left|\mathrm{L}(B)+\mathrm{L}\left(B^{\prime}\right)\right| \geq|\mathrm{L}(B)|+\left|\mathrm{L}\left(B^{\prime}\right)\right|-1 .
$$

(4) Suppose $\Omega\left(G_{0}, S\right) \not \subset \mathcal{G}_{k}(G)$. Then $\sigma(S) \in\left\langle G_{0}\right\rangle$ and $\sigma\left(S^{-1} S^{\prime}\right) \in\left\langle G_{0}\right\rangle$, so $\Omega\left(G_{0}, S^{-1} S^{\prime}\right) \not \subset \emptyset=\mathcal{G}_{0}(G)$ and we obtain a contradiction from (3) with $l=0$.

In the following lemma we investigate the effect of replacing an element $g_{1}+g_{2}$ occurring in an atom by the sequence $g_{1} g_{2}$.

Lemma 4.2. Let $g_{1}, g_{2} \in G, A \in \mathcal{A}(G)$ with $\left(g_{1}+g_{2}\right) \mid A$ and $B=$ $\left(g_{1}+g_{2}\right)^{-1} g_{1} g_{2} A \in \mathcal{B}(G)$.
(1) $\mathrm{L}(B) \subset\{1,2\}$.
(2) If $G=G_{1} \oplus G_{2}, g_{i} \in G_{i} \backslash\{0\}, A=\left(g_{1}+g_{2}\right) S_{1} S_{2}$ with $S_{i} \in \mathcal{F}\left(G_{i}\right)$ for $i \in\{1,2\}$, then $\mathrm{L}(B)=\{2\}$. In particular, $g_{i} S_{i} \in \mathcal{A}\left(G_{i}\right)$ for $i \in\{1,2\}$. Moreover, if $S_{i}^{\prime} \in \mathcal{F}\left(G_{i}\right)$ and $g_{i} S_{i}^{\prime} \in \mathcal{A}\left(G_{i}\right)$ for $i \in\{1,2\}$, then $\left(g_{1}+g_{2}\right) S_{1}^{\prime} S_{2}^{\prime} \in \mathcal{A}(G)$.
Proof. (1) Suppose that $\mathrm{L}(B) \not \subset\{1,2\}$. Then there exist $B_{1}, B_{2}, B_{3}$ $\in \mathcal{B}(G) \backslash\{1\}$ with $B=B_{1} B_{2} B_{3}$. Without restriction assume $g_{1} \mid B_{1}$ and $g_{1} g_{2} \mid B_{1} B_{2}$. Thus $\left(g_{1} g_{2}\right)^{-1}\left(g_{1}+g_{2}\right) B_{1} B_{2} \mid A$, a contradiction.
(2) By (1) it suffices to show that $B \notin \mathcal{A}(G)$. We have

$$
0=\sigma(B)=g_{1}+\sigma\left(S_{1}\right)+g_{2}+\sigma\left(S_{2}\right) .
$$

Thus $g_{i}+\sigma\left(S_{i}\right)=0$ and $g_{i} S_{i} \in \mathcal{B}(G)$ for $i \in\{1,2\}$. To prove the "moreover" part, it suffices to note that $S_{1}^{\prime} S_{2}^{\prime}$ is zero-sumfree.

In the following lemma we investigate $\Omega\left(G_{0}, S\right)$ for sequences $S \neq 1$ in $\mathcal{F}\left(G \backslash G_{0}\right)$ that are minimal with the property $\emptyset \neq \Omega\left(G_{0}, S\right)$. By Lemma 4.1(2) this means $\sigma(S) \in\left\langle G_{0}\right\rangle$ and $\sigma\left(S^{\prime}\right) \notin\left\langle G_{0}\right\rangle$ for every proper subsequence $1 \neq S^{\prime} \mid S$.

Lemma 4.3. Let $G_{0} \subset G$ be half-factorial and $S \in \mathcal{F}\left(G \backslash G_{0}\right) \backslash\{1\}$ minimal such that $\Omega\left(G_{0}, S\right) \neq \emptyset$, and let $k=\left|\mathrm{k}\left(\Omega\left(G_{0}, S\right) \cap \mathcal{A}(G)\right)\right|$. Then $\Omega\left(G_{0}, S\right) \subset \mathcal{G}_{k}(G)$ and there exists some $B_{k} \in \Omega\left(G_{0}, S\right)$ with $\left|\mathrm{L}\left(B_{k}\right)\right|=k$.

Proof. Let $B \in \Omega\left(G_{0}, S\right)$. We need to show that $|\mathrm{L}(B)| \leq k$. Let $B=$ $\prod_{i=0}^{n} U_{i}$ be a factorization of $B$ into atoms. Without restriction we assume $U_{0} \notin \mathcal{A}\left(G_{0}\right)$. Thus there exists some $1 \neq S^{\prime} \mid S$ such that $U_{0}=S^{\prime} F$ with $F \in$ $\mathcal{F}\left(G_{0}\right)$. Due to the minimality of $S$ we get $S^{\prime}=S$. Consequently, $U_{i} \in \mathcal{A}\left(G_{0}\right)$ and $\mathrm{k}\left(U_{i}\right)=1$ for each $i \in\{1, \ldots, n\}$. This implies that $n=\mathrm{k}(B)-\mathrm{k}\left(U_{0}\right)$ and

$$
|\mathrm{L}(B)| \leq\left|\left\{\mathrm{k}(A) \mid A \in \Omega\left(G_{0}, S\right) \cap \mathcal{A}(G)\right\}\right|=k .
$$

Let $\left\{A_{1}, \ldots, A_{k}\right\} \subset \Omega\left(G_{0}, S\right) \cap \mathcal{A}(G)$ be such that $\left|\mathrm{k}\left(\left\{A_{1}, \ldots, A_{k}\right\}\right)\right|=k$. By definition of $S$ we have $\sigma(S) \in\left\langle G_{0}\right\rangle$ and therefore there exists some $F \in \mathcal{F}\left(G_{0}\right)$ such that $\sigma(F)=(k-1) \sigma(S)$. We set $B_{k}=S^{-(k-1)} F \prod_{i=1}^{k} A_{i}$. Clearly, $\sigma\left(B_{k}\right)=0$ and $B_{k} \in \Omega\left(G_{0}, S\right)$. Moreover, $A_{i} \mid B_{k}$ for each $i \in$ $\{1, \ldots, k\}$. Thus we get $\mathrm{k}\left(B_{k}\right)-\mathrm{k}\left(A_{i}\right)+1 \in \mathrm{~L}\left(B_{k}\right)$ for each $i \in\{1, \ldots, k\}$, and $\left|\mathrm{L}\left(B_{k}\right)\right| \geq k$.
5. Results on half-factorial sets. In the proofs of our main results we will make use of several results on $\mu(G)$ and half-factorial subsets of finite abelian groups. In this section we summarize the known results we use and establish some new. Further results on half-factorial sets and proofs, in the present terminology, of most results we quote can be found in [3].

If $G$ is a cyclic group, say $G \cong C_{n}$, since every half-factorial set $G_{0} \subset G$ must also satisfy condition $\left(C_{0}\right)$, it follows that

$$
G_{0} \subset\{d g|1 \leq d| n\}
$$

for some $g \in G$ with $\operatorname{ord}(g)=n\left(\left[3\right.\right.$, Lemma 5.2]). Moreover, if $G_{0} \subset G$ with $\left|G_{0}\right|=\mu(G)$, then $\left\langle G_{0}\right\rangle=G$ (cf. [3, Proposition 3.5]). If $n$ is a prime power, possibly 1 , then the set on the right-hand side is half-factorial. Thus, if $G$ is a cyclic group with prime power order, say $|G|=p^{m}$, then $\mu(G)=m+1$ and if $G_{0} \subset G$ is a half-factorial set with $\left|G_{0}\right|=m+1$, then $G_{0}=\left\{p^{i} g \mid i \in\right.$ $\{0, \ldots, m\}\}$ for some $g \in G$ with $\operatorname{ord}(g)=p^{m}(c f .[23,24,26])$.

If $G$ is an elementary $p$-group with rank $\mathrm{r}(G)=r$, then (cf. [8, Theorem 8])

$$
1+\left\lfloor\frac{r}{2}\right\rfloor p+2\left(\frac{r}{2}-\left\lfloor\frac{r}{2}\right\rfloor\right) \leq \mu(G) \leq 1+\left\lfloor\frac{r}{2} p\right\rfloor,
$$

in particular if $r$ is even, then $\mu(G)=1+r p / 2$. Moreover, it is known that equality holds at the lower bound if $p \leq 7$ (cf. [18, 22]), and no example is known where equality does not hold.

The next lemma is essentially a reformulation of a result of L. Skula (cf. [23, Proposition 3.2]).

Lemma 5.1. Let $G$ be a finite abelian group and $G_{0} \subset G$ a half-factorial set with $\left|G_{0}\right|=\mu(G)$. Then $G_{0}$ is a subgroup if and only if $|G| \leq 2$.

Proof. In [23, Proposition 3.2] it is proved that a finite abelian group $G$ is a half-factorial set if and only if $|G| \leq 2$. This proves the "if" part. To obtain the "only if" part, assume $G_{0} \subset G$ is a subgroup and a half-factorial set with maximal cardinality as well. We have to show that $|G| \leq 2$. Again by [23, Proposition 3.2], we get $\left|G_{0}\right| \leq 2$, and $\mu(G) \leq 2$. Now, $G$ cannot contain any two independent elements $e_{1}$ and $e_{2}$, since in this case $\left\{0, e_{1}, e_{2}\right\} \subset G$ would be a half-factorial subset of $G$ with three elements, contradicting $\mu(G) \leq 2$. Therefore, $G$ is cyclic of prime power order. Since $\mu\left(C_{p^{m}}\right)=m+1$ (cf.
above), we get either $\mu(G)=1$ and $|G|=1$, or $\mu(G)=2$ and $|G| \in \mathbb{P}$. In the latter case a subset with two elements cannot be a subgroup unless $|G|=2$.

The following proposition extends Corollary 6.4.3 of [3].
Proposition 5.2. Let $p \in \mathbb{P}, m \in \mathbb{N}$ and $G \cong C_{p^{m}} \oplus C_{p^{m}}$. Further, let $\left\{e_{1}, e_{2}\right\}$ be a basis of $G$.
(1) $G_{0}=\bigcup_{i=0}^{m} p^{i}\left(e_{1}+\left\langle e_{2}\right\rangle\right)$ is a half-factorial set with $\left|G_{0}\right|=\mu(G)$, in particular

$$
\mu(G)=\frac{p^{m+1}-1}{p-1}
$$

(2) $\emptyset \neq \Omega\left(G_{0}, g\right) \subset \mathcal{G}_{1}(G)$, with $G_{0}$ as in (1), for every $g \in\left\langle e_{2}\right\rangle \backslash\{0\}$.

Proof. Let $\pi_{1}: G \rightarrow\left\langle e_{1}\right\rangle$ denote the projection on the first coordinate.
(1) By [3, Corollary 6.4.3] we know that $\mu(G) \leq \frac{p^{m+1}-1}{p-1}=\left|G_{0}\right|$ and thus it suffices to show that $G_{0}$ is half-factorial. Let $A \in \mathcal{A}\left(G_{0}\right)$; we will show that $\mathrm{k}(A)=1$. For each $g \in G_{0}$ we have $\operatorname{ord}(g)=\operatorname{ord}\left(\pi_{1}(g)\right)$. Therefore $\mathrm{k}(A)=\mathrm{k}\left(\pi_{1}(A)\right)$ and, since $\pi_{1}\left(G_{0}\right)=\left\{p^{i} e_{1} \mid i \in\{0, \ldots, m\}\right\} \subset\left\langle e_{1}\right\rangle$ is half-factorial and $\pi_{1}(A)$ is a block, we have $\mathrm{k}(A) \in \mathbb{N}$. By the main result of [6] we have $\mathrm{k}(A) \leq \mathrm{K}(G)=2-1 / p^{m}$ and thus $\mathrm{k}(A)=1$.
(2) Let $g \in\left\langle e_{2}\right\rangle \backslash\{0\}$. Since $\left\langle G_{0}\right\rangle=G$, it suffices to verify that $\Omega\left(G_{0}, g\right) \subset$ $\mathcal{G}_{1}(G)$. Let $A \in \Omega\left(G_{0}, g\right) \cap \mathcal{A}(G)$. Then $A=g F$ with $F \in \mathcal{F}\left(G_{0}\right)$ zerosumfree and clearly $F \neq 1$. Since $\pi_{1}(F)$ is a zero-sum sequence, we deduce as in (1) that $\mathrm{k}(F)=1$ and thus $\mathrm{k}(A)=1 / \operatorname{ord}(g)+1$. By Lemma 4.3 this implies the statement.

In Proposition 5.4 we will determine the structure of generating halffactorial sets in $C_{4}^{r}$. First we recall two results, which we need in the proof of this proposition.

In [4, Lemma 2.1] it is proved that if $G \cong C_{p^{m}}^{r}$ with $p \in \mathbb{P}$ and $m, r \in \mathbb{N}$, then every generating subset $G_{0} \subset G$ contains a basis $G_{1} \subset G_{0}$.

The following lemma (cf. [3, Lemma 3.6]) provides results on halffactorial sets that consist of independent elements of equal order and at most two additional elements.

Lemma 5.3. Let $G \cong C_{n}^{r}$ with $n, r \in \mathbb{N},\left\{e_{1}, \ldots, e_{r}\right\}$ a basis of $G$, and $a=\sum_{i=1}^{r} a_{i} e_{i}, a^{\prime}=\sum_{i=1}^{r} a_{i}^{\prime} e_{i} \in G$ distinct elements with $\operatorname{ord}(a)=\operatorname{ord}\left(a^{\prime}\right)$ and $a_{i}, a_{i}^{\prime} \in\{1, \ldots, n\}$ for each $i \in\{1, \ldots, r\}$.
(1) If $\left\{a, e_{1}, \ldots, e_{r}\right\}$ is a half-factorial set, then $\sum_{i=1}^{r}\left(n-a_{i}\right)=n-$ $\operatorname{gcd}\left\{a_{1}, \ldots, a_{r}, n\right\}$.
(2) If $\left\{a, a^{\prime}, e_{1}, \ldots, e_{r}\right\}$ is a half-factorial set and $a_{i}=a_{i}^{\prime}$ for some $i \in$ $\{1, \ldots, r\}$, then $\operatorname{ord}\left(a_{i} e_{i}\right)<\operatorname{ord}(a)$.

Proposition 5.4. Let $G \cong C_{4}^{r}$ with $r \in \mathbb{N}$ and let $G_{0} \subset G$ be a generating set. The set $G_{0}$ is half-factorial if and only if there exists a basis $G_{1}=\left\{e_{1}, \ldots, e_{r}\right\}, s, t \in \mathbb{N}_{0}$ with $r=3 s+t$, and a map from $\{1, \ldots, t\}$ to itself such that

$$
\begin{aligned}
G_{0} \subset\{0\} & \cup \bigcup_{j=1}^{t}\left\{e_{j}, 2 e_{j}, 3 e_{j}+2 e_{f(j)}\right\} \\
& \cup \bigcup_{i=0}^{s-1}\left\{e_{3 i+t+1}, e_{3 i+t+2}, e_{3 i+t+3}, 3 e_{3 i+t+1}+3 e_{3 i+t+2}+3 e_{3 i+t+3}\right\}
\end{aligned}
$$

Proof. First we prove the "if" part. Let $\left\{e_{1}, \ldots, e_{r}\right\} \subset G$ be a basis, $s, t \in \mathbb{N}_{0}$ with $3 s+t=r$, and $f$ a map from $\{1, \ldots, t\}$ to itself. For $i \in$ $\{0, \ldots, s-1\}$ we set

$$
H_{i}=\left\{e_{3 i+t+1}, e_{3 i+t+2}, e_{3 i+t+3}, 3 e_{3 i+t+1}+3 e_{3 i+t+2}+3 e_{3 i+t+3}\right\}
$$

and we set $F_{0}=\bigcup_{j=1}^{t}\left\{e_{j}, 2 e_{j}, 3 e_{j}+2 e_{f(j)}\right\}$. We show that $G_{0}^{\prime}=\{0\} \cup F_{0} \cup$ $\bigcup_{i=0}^{s-1} H_{i}$ is half-factorial. Since $\mathcal{A}\left(G_{0}^{\prime}\right)=\{0\} \cup \mathcal{A}\left(F_{0}\right) \cup \bigcup_{i=0}^{s-1} \mathcal{A}\left(H_{i}\right)$, it suffices to show that $H_{i}$ is half-factorial for each $i \in\{0, \ldots, s-1\}$ and that $F_{0}$ is half-factorial. For $i \in\{0, \ldots, s-1\}$ we have

$$
\mathcal{A}\left(H_{i}\right)=\left\{h^{4} \mid h \in H_{i}\right\} \cup\left\{\left(3 e_{3 i+t+1}+3 e_{3 i+t+2}+3 e_{3 i+t+3}\right) \prod_{l=1}^{3} e_{3 i+t+l}\right\}
$$

thus each atom has cross number 1 and $H_{i}$ is half-factorial.
Let $A \in \mathcal{A}\left(F_{0}\right)$; we have to show that $\mathrm{k}(A)=1$. If $\left(3 e_{j}+2 e_{f(j)}\right) \nmid A$ for each $j \in\{1, \ldots, t\}$ with $f(j) \neq j$, then $A \in \mathcal{A}\left(\left\{e_{l}, 2 e_{l}\right\}\right)$ for some $l \in$ $\{1, \ldots, t\}$ and it follows immediately that $\mathrm{k}(A)=1$. Thus assume without restriction that $f(1) \neq 1$ and $g=\left(3 e_{1}+2 e_{f(1)}\right) \mid A$. We set $n=f(1)$. Clearly, $\mathrm{v}_{g}(A) \leq 4$ and if $\mathrm{v}_{g}(A)=4$, then $A=g^{4}$ and $\mathrm{k}(A)=1$. We distinguish two cases.

CASE 1: $\mathrm{v}_{g}(A)=2$. If $e_{1}^{2} \mid A$ or $\left(2 e_{1}\right) \mid A$, it follows that $A=e_{1}^{2} g^{2}$, respectively $A=\left(2 e_{1}\right) g^{2}$, and we are done. Thus assume $e_{1}^{2} \nmid A$ and $\left(2 e_{1}\right) \nmid A$. Since the sum of $A$ is zero, there exists some $l \in\{2, \ldots, t\}$ such that $f(l)=1$ and $\left(3 e_{l}+2 e_{1}\right) \mid A$ with odd multiplicity. Therefore $e_{l} \mid A$ and consequently $A=g^{2}\left(3 e_{l}+2 e_{1}\right) e_{l}$ and $\mathrm{k}(A)=1$.

CASE 2: $\mathrm{v}_{g}(A) \in\{1,3\}$. It follows that $e_{1} \mid A$. If $e_{n}^{2} \mid A$ or $\left(2 e_{n}\right) \mid A$, we have $A=g e_{1} e_{n}^{2}$, respectively $A=g e_{1}\left(2 e_{n}\right)$, and we are done. Thus assume there exists some $m \in\{2, \ldots, t\} \backslash\{n\}$ with $f(m)=n$ and $\left(3 e_{m}+2 e_{n}\right) \mid A$ with odd multiplicity. This implies that $e_{m} \mid A$ and $A=g\left(3 e_{m}+2 e_{n}\right) e_{1} e_{m}$.

Next we prove the "only if" part. Let $G_{0} \subset G$ be a generating halffactorial set. Then there exists a basis $G_{1}=\left\{e_{1}, \ldots, e_{r}\right\} \subset G_{0}$. For $g \in$ $G_{0} \backslash G_{1}$ it follows by Lemma 5.3 that either $g=0, g=2 e_{i}, g=3 e_{i}+2 e_{j}$,
or $g=3 e_{i}+3 e_{j}+3 e_{l}$ for distinct $i, j, l \in\{1, \ldots, r\}$. Moreover, for each $i \in\{1, \ldots, r\}$ there exists at most one element $g_{i} \in G_{0}$ such that $g_{i}=$ $3 e_{i}+\sum_{j=1, j \neq i}^{r} b_{j} e_{j}$ with $b_{j} \in\{0,1,2,3\}$. Thus it remains to show that if $g=3 e_{i}+3 e_{j}+3 e_{l} \in G_{0}$ with distinct $i, j, l \in\{1, \ldots, r\}$, then there is no $h=2 e_{i}+\sum_{\nu=1, \nu \neq i}^{r} b_{\nu}^{\prime} e_{\nu} \in G_{0}$ with $b_{\nu}^{\prime} \in\{0,3\}$. Assume to the contrary that such an element exists. We consider the atom $A=g^{2} h \prod_{\nu=1, \nu \neq i}^{r} e_{\nu}^{c_{\nu}}$ with $c_{\nu} \in\{0,1,2,3\}$ uniquely determined by independence. We have $c_{j} \equiv 2-b_{j}^{\prime}$ $(\bmod 4)$ and $c_{l} \equiv 2-b_{l}^{\prime}(\bmod 4)$, hence the cross number of $A$ is greater than 1 , a contradiction.

In particular, this proposition shows that the maximal cardinality of a generating half-factorial set in $C_{4}^{r}$ with $r \geq 2$ is $1+3 r$. Thus for $p^{m}=4$ and $r \geq 2$ the upper bound derived in [3, Proposition 3.7] for the cardinality of a generating half-factorial set in $C_{p^{m}}^{r}$ is sharp.
6. Positivity of $\psi_{k}(G)$ for $k \geq 2$. In this section we show that the invariants $\psi_{k}(G)$ for $k \geq 2$ are all positive.

Theorem 6.1. Let $G$ be a finite abelian group with $|G| \geq 3$ and let $k \geq 2$ be an integer. Then $\psi_{k}(G)>0$.

Proof. From the definition of $\psi_{k}(G)$ it follows that $\psi_{k+1}(G) \geq \psi_{k}(G)$ for every $k \in \mathbb{N}$. Therefore it is enough to consider the case $k=2$. Let $G_{0} \subset G$ be half-factorial with $\left|G_{0}\right|=\mu(G)$. By Lemma 5.1 there exist $g_{1}, g_{2} \in G_{0}$ (possibly $g_{1}=g_{2}$ ) such that $g_{1}+g_{2} \notin G_{0}$. Clearly, $g_{1}+g_{2} \in\left\langle G_{0}\right\rangle$ and Lemma 4.1 shows that $\Omega\left(G_{0}, g_{1}+g_{2}\right) \neq \emptyset$. We assert that

$$
\Omega\left(G_{0}, g_{1}+g_{2}\right) \subset \mathcal{G}_{2}(G)
$$

By Lemma 4.3 it suffices to prove that $\left|\mathrm{k}\left(\Omega\left(G_{0}, g_{1}+g_{2}\right) \cap \mathcal{A}(G)\right)\right| \leq 2$. Let $A \in \Omega\left(G_{0}, g_{1}+g_{2}\right) \cap \mathcal{A}(G)$. We show that

$$
\mathrm{k}(A) \in\left\{\left.j-\frac{1}{\operatorname{ord}\left(g_{1}\right)}-\frac{1}{\operatorname{ord}\left(g_{2}\right)}+\frac{1}{\operatorname{ord}\left(g_{1}+g_{2}\right)} \right\rvert\, j \in\{1,2\}\right\} .
$$

We consider the block $B=\left(g_{1}+g_{2}\right)^{-1} g_{1} g_{2} A \in \mathcal{B}\left(G_{0}\right)$. Clearly,

$$
\mathrm{k}(B)=\mathrm{k}(A)+\frac{1}{\operatorname{ord}\left(g_{1}\right)}+\frac{1}{\operatorname{ord}\left(g_{2}\right)}-\frac{1}{\operatorname{ord}\left(g_{1}+g_{2}\right)}
$$

and by Lemma 4.2 we have $\mathrm{L}(B) \subset\{1,2\}$. Since $G_{0}$ is half-factorial, this implies $\mathrm{k}(B) \in\{1,2\}$. Consequently, $\emptyset \neq \Omega\left(G_{0}, g_{1}+g_{2}\right) \subset \mathcal{G}_{2}(G)$ and $\psi_{2}(G)>0$.
7. Positivity of $\psi_{1}(G)$. In this section we establish results on the positivity of $\psi_{1}(G)$. If $\mu(G)$ and some half-factorial set $G_{0} \subset G$ with $\left|G_{0}\right|=\mu(G)$ are known, then it is usually not difficult to give an example of a sequence
$S \in \mathcal{F}\left(G \backslash G_{0}\right) \backslash\{1\}$ such that $\emptyset \neq \Omega\left(G_{0}, S\right) \subset \mathcal{G}_{1}(G)$, and thus to obtain $\psi_{1}(G)>0$. Since for most groups $\mu(G)$ is not known, we are not able to prove $\psi_{1}(G)>0$ in general. But we will prove the positivity in several special cases.

Theorem 7.1. We have $\psi_{1}(G)>0$ for every finite abelian group $G$ with $|G| \geq 3$ satisfying at least one of the following conditions:
(1) $G \cong C_{p^{m}}$ for $p \in \mathbb{P}$ and $m \in \mathbb{N}$.
(2) $G \cong C_{p^{m} q^{n}}$ for $p, q \in \mathbb{P}$ and $m, n \in \mathbb{N}$.
(3) $G \cong C_{p^{m}} \oplus C_{p^{m}}$ for $p \in \mathbb{P}$ and $m \in \mathbb{N}$.
(4) $G$ is an elementary $p$-group with even rank.
(5) $G$ is an elementary $p$-group with odd rank and $\mu(G)=2+\frac{\mathrm{r}(G)-1}{2} p$.
(6) $G$ is an elementary p-group and $r(G)>r_{p}$ for some $r_{p} \in \mathbb{N}_{0}$.
(7) $G$ is an elementary $p$-group with exponent $p \leq 7$.
(8) $G \cong C_{4}^{r}$ for $r \in \mathbb{N}$.
(9) $|G| \leq 95$.

Before proving this theorem, we prove the positivity of $\psi_{1}(G)$ assuming different properties for some half-factorial set with maximal cardinality (Proposition 7.2). Many groups for which $\mu(G)$ is known have some halffactorial subset with maximal cardinality satisfying one of the conditions of Proposition 7.2, and this will be used in the proof of Theorem 7.1.

Proposition 7.2. Let $G_{0} \subset G$ be a half-factorial set with $\left|G_{0}\right|=\mu(G)$.
(1) If there exist $\{0\} \subsetneq G_{0}^{\prime}, G_{0}^{\prime \prime} \subset G_{0}$ such that $G_{0}=G_{0}^{\prime} \cup G_{0}^{\prime \prime}$ and $\left\langle G_{0}\right\rangle=\left\langle G_{0}^{\prime}\right\rangle \oplus\left\langle G_{0}^{\prime \prime}\right\rangle$, then $\psi_{1}(G)>0$.
(2) If there exists some $g \in G_{0}$ such that $\left\langle G_{0} \backslash\{g\}\right\rangle \neq G$, then $\psi_{1}(G)>0$. In particular, if $\left\langle G_{0}\right\rangle \neq G$, then $\psi_{1}(G)>0$.
Proof. (1) Let $g^{\prime} \in G_{0}^{\prime} \backslash\{0\}$ and $g^{\prime \prime} \in G_{0}^{\prime \prime} \backslash\{0\}$. By Lemma 4.2(2) we have $\emptyset \neq \Omega\left(G_{0}, g^{\prime}+g^{\prime \prime}\right) \subset \mathcal{G}_{1}(G)$ and the statement follows.
(2) Suppose $g \in G_{0}$ with $\left\langle G_{0} \backslash\{g\}\right\rangle \neq G$. We consider two cases.

CASE 1: $g \in\left\langle G_{0} \backslash\{g\}\right\rangle$. Since $\left\langle G_{0}\right\rangle=\left\langle G_{0} \backslash\{g\}\right\rangle \neq G$, there exists some $h \in G \backslash\left\langle G_{0}\right\rangle$. We have $-h \in G \backslash\left\langle G_{0}\right\rangle$ and, since $\sigma(-h h)=0$, we have $-h h \in \Omega\left(G_{0},-h h\right)$. Moreover, $\Omega\left(G_{0},-h h\right) \cap \mathcal{A}(G)=\{-h h\}$ and applying Lemma 4.3 we get $\emptyset \neq \Omega\left(G_{0},-h h\right) \subset \mathcal{G}_{1}(G)$ and $\psi_{1}(G) \geq|-h h|>0$.

CASE 2: $g \notin\left\langle G_{0} \backslash\{g\}\right\rangle$. Clearly, $-g \notin\left\langle G_{0} \backslash\{g\}\right\rangle$, and $-g=g$ if and only if $\operatorname{ord}(g)=2$. If $-g=g$, then $\left\langle G_{0}\right\rangle=\langle g\rangle \oplus\left\langle G_{0} \backslash\{g\}\right\rangle$ and $\psi_{1}(G)>0$ by (1). Thus we assume $-g \neq g$. Then $-g \notin G_{0}$ and $\Omega\left(G_{0},-g\right) \cap \mathcal{A}(G)=\{-g g\}$. By Lemma 4.3 we have $\emptyset \neq \Omega\left(G_{0},-g\right) \subset \mathcal{G}_{1}(G)$.

Since $G_{0} \neq \emptyset$, the "in particular" statement is obvious. -
There are examples of groups that have a half-factorial subset with maximal cardinality that does not generate the group (cf. [3, Corollary 6.5]) and
thus Proposition $7.2(2)$ can be used to obtain further examples of groups with $\psi_{1}(G)>0$.

Proposition $7.2(1)$ implies $\psi_{1}(G)>0$ for all groups $G=G^{\prime} \oplus G^{\prime \prime}$ with $\mu(G)=\mu\left(G^{\prime}\right)+\mu\left(G^{\prime \prime}\right)-1$, since $G_{0}=G_{0}^{\prime} \cup G_{0}^{\prime \prime}$, where $G_{0}^{\prime} \subset G^{\prime}$ is half-factorial with $\left|G_{0}^{\prime}\right|=\mu\left(G^{\prime}\right)$, and $G_{0}^{\prime \prime} \subset G^{\prime \prime}$ is half-factorial with $\left|G_{0}^{\prime \prime}\right|=\mu\left(G^{\prime \prime}\right)$, fulfills the conditions.

The following corollary provides equivalent conditions for $\psi_{1}(G)=0$.
Corollary 7.3. Let $G$ be a finite abelian group. The following statements are equivalent:
(1) $\psi_{1}(G)=0$.
(2) For every half-factorial $G_{0} \subset G$ with $\left|G_{0}\right|=\mu(G)$ and for every $S \in \mathcal{F}\left(G \backslash G_{0}\right) \backslash\{1\}$ we have $\Omega\left(G_{0}, S\right) \not \subset \mathcal{G}_{1}(G)$.
(3) For every half-factorial $G_{0} \subset G$ with $\left|G_{0}\right|=\mu(G)$ and for every $g \in G \backslash G_{0}$ we have $\Omega\left(G_{0}, g\right) \not \subset \mathcal{G}_{1}(G)$.
(4) For every half-factorial $G_{0} \subset G$ with $\left|G_{0}\right|=\mu(G)$ and for every $g \in G \backslash G_{0}$ we have $\left|\mathrm{k}\left(\Omega\left(G_{0}, g\right) \cap \mathcal{A}(G)\right)\right|>1$.

Proof. We can assume that $\left\langle G_{0}\right\rangle=G$ for every half-factorial $G_{0} \subset G$ with $\left|G_{0}\right|=\mu(G)$, since otherwise statement (1) is false by Proposition 7.2 and (2)-(4) are obviously false as well.

Hence, $\Omega\left(G_{0}, S\right) \neq \emptyset$ for every $S \in \mathcal{F}\left(G \backslash G_{0}\right)$ by Lemma 4.1. Statements (1) and (2) are equivalent by definition of $\psi_{1}(G)$. (3) and (4) are equivalent by Lemma 4.3. Statement (3) is a special case of (2). Thus it remains to show that (3) implies (2). Let $G_{0} \subset G$ be half-factorial with $\left|G_{0}\right|=\mu(G)$. Further, let $S \in \mathcal{F}\left(G \backslash G_{0}\right) \backslash\{1\}$ and let $g \mid S$. By assumption we have $\Omega\left(G_{0}, g\right) \not \subset \mathcal{G}_{1}(G)$ and $\Omega\left(G_{0}, S\right) \neq \emptyset$, so $\Omega\left(G_{0}, S\right) \not \subset \mathcal{G}_{1}(G)$ by Lemma 4.1.

We proceed to prove the main result of this section. We make use of the results on half-factorial sets given in Section 5 without further reference.

Proof of Theorem 7.1. (1) Let $G \cong C_{p^{m}}$ with $p \in \mathbb{P}$ and $m \in \mathbb{N}$. Further let $G_{0} \subset G$ be half-factorial with $\left|G_{0}\right|=\mu(G)$. Then $G_{0}=\left\{p^{i} g \mid i \in\right.$ $\{0, \ldots, m\}\}$ for some $g \in G$ with ord $(g)=p^{m}$. Thus $G_{0}$ fulfills the conditions of Proposition $7.2(2)$ and we are done.
(2) Let $G \cong C_{p^{m} q^{n}}$ with $p, q \in \mathbb{P}, p<q$ and $m, n \in \mathbb{N}$. Let $G_{0} \subset G$ be half-factorial with $\left|G_{0}\right|=\mu(G)$. Then $\left\langle G_{0}\right\rangle=G$ and there exists a generating element $g$ of $G$ such that

$$
G_{0} \subset\left\{d g|1 \leq d| p^{m} q^{n}\right\}=G_{0}^{\prime}
$$

First we show that $\left|\mathrm{k}\left(\Omega\left(G_{0}^{\prime}, 2 p^{m} g\right) \cap \mathcal{A}(G)\right)\right| \leq 1$. Let $A \in \Omega\left(G_{0}^{\prime}, 2 p^{m} g\right)$ be an atom and $B=\left(p^{m} g\right)^{2}\left(2 p^{m} g\right)^{-1} A$. Since $B \in \mathcal{B}\left(G_{0}^{\prime}\right), B \neq 1$, and $G_{0}^{\prime}$ satisfies condition $\left(C_{0}\right)$, we have $\mathrm{k}(B)=l$ for a positive integer $l$. Hence $\mathrm{k}(A)=\mathrm{k}(B)-1 / q^{n}=l-1 / q^{n}$. On the other hand, $\mathrm{k}(A) \leq \mathrm{K}(G)$ and by $[9$,

Theorem 2] we know that

$$
\mathrm{K}(G)=\frac{p^{m}-1}{p^{m}}+\frac{q^{n}-1}{q^{n}}+\frac{1}{p^{m} q^{n}} .
$$

Thus $\mathrm{k}(A)=1-1 / q^{n}$. Since $G_{0} \subset G_{0}^{\prime}$, it follows that $\Omega\left(G_{0}, S\right) \subset \Omega\left(G_{0}^{\prime}, S\right)$ and thus clearly $\left|\mathrm{k}\left(\Omega\left(G_{0}, 2 p^{m} g\right) \cap \mathcal{A}(G)\right)\right| \leq 1$. This implies $\Omega\left(G_{0}, 2 p^{m} g\right) \subset$ $\mathcal{G}_{1}(G)$ by Lemma 4.3. Since $\left\langle G_{0}\right\rangle=G$, we have $\Omega\left(G_{0}, 2 p^{m} g\right) \neq \emptyset$ and the result follows.
(3) Let $G \cong C_{p^{m}} \oplus C_{p^{m}}$ with $p \in \mathbb{P}$ and $m \in \mathbb{N}$. By Proposition 5.2 there exists a half-factorial subset $G_{0} \subset G$ with maximal cardinality and an element $g \in G \backslash G_{0}$ such that $\emptyset \neq \Omega\left(G_{0}, g\right) \subset \mathcal{G}_{1}(G)$. Thus the statement follows immediately.
(4) Let $G$ be an elementary $p$-group with even rank. If $\mathrm{r}(G)=2$, then the result follows by (3). Suppose $\mathrm{r}(G) \geq 4$. Then there exist subgroups $G^{\prime}, G^{\prime \prime}$ such that $G=G^{\prime} \oplus G^{\prime \prime}$ and $\mu(G)=\mu\left(G^{\prime}\right)+\mu\left(G^{\prime \prime}\right)-1$. Thus the statement follows by Proposition 7.2(1).
(5) Let $G$ be an elementary $p$-group with odd rank and $\mu(G)=2+$ $\frac{\mathrm{r}(G)-1}{2} p$. If $\mathrm{r}(G)=1$, then the statement follows by (1). Suppose $\mathrm{r}(G) \geq 3$. Then $G=G^{\prime} \oplus G^{\prime \prime}$ with $r\left(G^{\prime}\right)=1$. By assumption $\mu(G)=\mu\left(G^{\prime}\right)+\mu\left(G^{\prime \prime}\right)-1$ and the statement follows by Proposition 7.2(1).
(6) For $s \in \mathbb{N}_{0}$ let $\delta(s)=\mu\left(C_{p}^{2 s+1}\right)-2-s p \in \mathbb{Z}$. We know $\delta(s) \in$ $\{0, \ldots,(p-1) / 2\}$ and $\delta(\cdot)$ is a non-decreasing function. Let $s_{p} \in \mathbb{N}$ be such that $\delta\left(s_{p}\right)=\max \left\{\delta(s) \mid s \in \mathbb{N}_{0}\right\}$; then $\delta(s)=\delta\left(s_{p}\right)$ for every $s \geq s_{p}$. We set $r_{p}=2 s_{p}+1$. Let $\mathrm{r}(G)=r>r_{p}$. If $r$ is even, the assertion is already proved in (4). Suppose $r$ is odd. Let $G=G^{\prime} \oplus G^{\prime \prime}$ with $\mathrm{r}\left(G^{\prime}\right)=r-r_{p}$ and $\mathrm{r}\left(G^{\prime \prime}\right)=r_{p}$. Then $\mu(G)=\mu\left(G^{\prime}\right)+\mu\left(G^{\prime \prime}\right)-1$ and thus by Proposition 7.2(1) the statement follows.
(7) Let $G$ be an elementary $p$-group with $p \leq 7$. If $\mathrm{r}(G)$ is even, then the statement follows by (4). If $r(G)$ is odd, then $\mu(G)=2+\frac{r-1}{2} p$, which implies the assertion by (5).
(8) Let $G \cong C_{4}^{r}$ with $r \in \mathbb{N}$. For $r=1$ the statement follows by (1) and for $r=2$ by (3). Suppose $r \geq 3$. If $\mu(G)>1+3 r$, it follows by Proposition 5.4 that a half-factorial set with maximal cardinality does not generate $G$, and the statement follows by $7.2(2)$.

Assume $\mu(G)=1+3 r$. If $r \geq 4$, there exist $s, t \geq 2$ and two subgroups $G^{\prime} \cong C_{4}^{s}, G^{\prime \prime} \cong C_{4}^{t}$ of $G$ such that $G=G^{\prime} \oplus G^{\prime \prime}$. It follows that

$$
1+3 r=\mu(G) \geq \mu\left(G^{\prime}\right)+\mu\left(G^{\prime \prime}\right)-1 \geq 1+3(s+t)=1+3 r .
$$

Thus the statement follows by $7.2(1)$. It remains to consider $r=3$. Let $\left\{e_{1}, e_{2}, e_{3}\right\} \subset G$ be a basis. Further let $G_{0}=\left\{0, e_{1}, e_{2}, e_{3}, 2 e_{1}, 2 e_{2}, 2 e_{3}, 3 e_{1}+\right.$ $\left.2 e_{2}, 3 e_{2}+2 e_{3}, 3 e_{3}+2 e_{1}\right\}$. By Proposition 5.4 this set is half-factorial and by our assumption on $\mu(G)$ it has maximal cardinality. Let $g=2 e_{1}+2 e_{2}+2 e_{3}$.

We assert that $\emptyset \neq \Omega\left(G_{0}, g\right) \subset \mathcal{G}_{1}(G)$, which implies the statement immediately. Clearly, $\Omega\left(G_{0}, g\right)$ is non-empty and by Lemma 4.3 it suffices to show that each atom in it has the same cross number. Let $A \in \Omega\left(G_{0}, g\right) \cap \mathcal{A}(G)$. We assert that $\mathrm{k}(A)=2$. We observe that if $e_{i}^{2} \mid A$, then $A^{\prime}=\left(2 e_{i}\right) e_{i}^{-2} A$ has the same cross number as $A$ and is a zero-sum sequence. Since every factorization of $A^{\prime}$ yields a factorization of $A$, it follows that $A^{\prime}$ is an atom. Similarly, if $\left(3 e_{i}+2 e_{j}\right)^{2} \mid A$ or $e_{i}\left(3 e_{i}+2 e_{j}\right) \mid A$, then $\left(2 e_{i}\right)\left(3 e_{i}+2 e_{j}\right)^{-2} A$, respectively $\left(2 e_{j}\right) e_{i}^{-1}\left(3 e_{i}+2 e_{j}\right)^{-1} A$, is an atom with the same cross number.

Note that $\mathrm{v}_{e_{i}}(A) \equiv \mathrm{v}_{3 e_{i}+2 e_{j}}(A)(\bmod 2)$ for each $i \in\{1,2,3\}$ and $j$ such that $3 e_{i}+2 e_{j} \in G_{0}$. Thus by repeated application of these replacements, we obtain an atom $A^{*} \in \Omega\left(G_{0}, g\right)$ such that $\mathrm{k}(A)=\mathrm{k}\left(A^{*}\right)$ and none of $\left\{e_{1}, e_{2}, e_{3}, 3 e_{1}+2 e_{2}, 3 e_{2}+2 e_{3}, 3 e_{3}+2 e_{1}\right\}$ divides $A^{*}$. Thus $A^{*}=$ $g\left(2 e_{1}\right)\left(2 e_{2}\right)\left(2 e_{3}\right)$ and $\mathrm{k}(A)=\mathrm{k}\left(A^{*}\right)=2$.
(9) The proof uses computational methods. First we determine all halffactorial subsets $G_{0}$ with maximal cardinality. This is done by examining the atoms in $\mathcal{F}\left(G_{0}^{\prime}\right)$, where $G_{0}^{\prime} \subset G$ is a subset satisfying condition $\left(C_{0}\right)$. Then we pick one such subset $G_{0}$, find all the zero-sumfree sequences in $\mathcal{F}\left(G_{0}\right)$, and check whether there exists a $g \in G \backslash G_{0}$ such that all zero-sumfree $S$ with $\sigma(S)=-g$ have the same cross number. If we can find such a $g$ for at least one $G_{0}$, the assertion $\psi_{1}(G)>0$ is proved. The details can be found at http://www.amu.edu.pl/ ${ }^{\text {m maciejr. }}$

Addendum. Recently, A. Plagne and the second author proved that $\mu\left(C_{p}^{r}\right)=2+\frac{r-1}{2} p$ for $p \in \mathbb{P}$ and $r$ odd. Thus, every elementary $p$-group with odd rank fulfils condition (5) of Theorem 7.1, and consequently $\psi_{1}(G)>0$ if $G$ is an elementary $p$-group.
