

## A conjecture on Khovanov's invariants

by

Stavros Garoufalidis (Atlanta, GA)

**Abstract.** We formulate a conjectural formula for Khovanov's invariants of alternating knots in terms of the Jones polynomial and the signature of the knot.

**1. A conjecture.** This note was initially written as an appendix to a paper of Bar-Natan, who explains the beautiful ideas of Khovanov's on a categorification of the Jones polynomial, [Kh1, Kh2]. Hence, we will assume familiarity with [B], the notation of which we will use below.

Given a knot  $L$ , we will denote by  $\text{Kh}(L) \in BZ[t^{\pm 1}, q^{\pm}]$  the generating series of the ranks of the Khovanov homology of  $L$ , using rational coefficients.

It follows by the definition of  $\text{Kh}$  that

$$(1) \quad \text{Kh}(-1, q) = (q + q^{-1})J(q),$$

where  $J$  is the Jones polynomial, normalized by  $J(\text{unknot}) = 1$ . We formulate a conjecture regarding the opposite specialization  $\text{Kh}(t, 1)$  of  $\text{Kh}(t, q)$ :

CONJECTURE 1. *For all alternating knots  $L$ , we have*

$$(2) \quad \text{Kh}(t, 1) = 1 + J(it^{1/2})(it^{1/2})^{-\sigma},$$

where  $i = \sqrt{-1}$  and  $\sigma$  is the signature of the knot.

Bar-Natan, Khovanov and the author have formulated a restriction on the support of the  $\text{Kh}$  invariants, as follows:

CONJECTURE 2. *For all alternating knots  $L$ , the support of  $\text{Kh}$  lies in the lines  $\deg(q) = 2 \deg(t) + \sigma \pm 1$ .*

These restrictions are enough to determine the Khovanov invariants in terms of the Jones polynomial and the signature, as follows.

2000 *Mathematics Subject Classification*: Primary 57N10; Secondary 57M25.

*Key words and phrases*: Jones polynomial, signature, Khovanov's invariants.

The author was supported in part by National Science Foundation.

PROPOSITION 1.1. *If a knot satisfies Conjectures 1 and 2, then*

$$\begin{aligned} \text{Kh}(t, q) \\ = \frac{q^\sigma}{qt^{1/2} + q^{-1}t^{-1/2}} (J(it^{1/2})(it^{1/2})^{-\sigma} (q^2t^{1/2} + q^{-2}t^{-1/2}) + t^{1/2} + t^{-1/2}). \end{aligned}$$

*Proof.* Conjecture 2 implies that we can write

$$\text{Kh}(t, q) = \sum_n q^{2n+\sigma} t^n (qa_n + q^{-1}b_n) = q^\sigma (qA(q^2t) + q^{-1}B(q^2t))$$

for some Laurent polynomials  $A$  and  $B$ . Equations (1) and (2) are linear equations on  $A$  and  $B$ , which can be solved explicitly. The result follows. ■

COROLLARY 1.2. *If a knot satisfies Conjectures 1 and 2, then the Khovanov invariant determines the Jones polynomial and its signature, and vice versa.*

*Proof.* Conjecture 1 together with equation (1) implies that  $\text{Kh}$  determines  $J$  and  $\sigma$ . The converse follows from Proposition 1.1. ■

Here is a numerical example of the simplest nontrivial alternating knot, a trefoil  $3_1$ .

EXAMPLE 1.3. For the trefoil, we have  $\text{Kh}(t, q) = q + q^3 + t^2q^5 + t^3q^9$ ,  $J(q) = q^2 + q^6 - q^8$  and  $\sigma = 2$ .

Which knots satisfy Conjectures 1 and 2?

REMARK 1.4. The computer calculations of Bar-Natan [B] show that Conjectures 1 and 2 are true for all alternating knots with at most 10 crossings and for most (but not all) nonalternating knots with at most 10 crossings. Both conjectures fail on the same set

$$\{8_{19}, 9_{42}, 10_{124}, 10_{128}, 10_{132}, 10_{136}, 10_{139}, 10_{145}, 10_{152}, 10_{153}, 10_{154}, 10_{161}\}$$

of knots up to 10 crossings. It is remarkable that both conjectures (which are superficially independent) fail on the same small set of knots.

The next remark gives an alternative form of Conjecture 1 in terms of the special value of  $\text{Kh}(t, -1)$ . This special value is in some sense an Euler characteristic rather than a Poincaré polynomial.

REMARK 1.5. Consider a knot that satisfies Conjecture 2. Then it satisfies Conjecture 1 iff

$$(3) \quad \text{Kh}(t, -1) = -1 - J(it^{1/2})(it^{1/2})^{-\sigma}.$$

This follows easily from the fact that  $J(q)$  is an even function of  $q$  and that  $\sigma$  is an even integer.
