On squares of squares II

by

ANDREW BREMNER (Tempe, AZ)

0. The problem of determining whether there can exist a $3 \times 3$ magic square whose entries are perfect squares is an intriguing one, and has been discussed by several authors, including Bremner [3], Gardner [6], Guy & Nowakowski [7], LaBar [9], Robertson [10], Sallows [11]. There are two underlying problems. First, to find $3 \times 3$ squares all of whose entries are square, and with as many row, column, and diagonal sums as possible being equal. Second, to find $3 \times 3$ magic squares with as many entries as possible being perfect squares. The first problem was discussed in some detail in Bremner [3], and it is the intention of this current writing to address the second problem. A $3 \times 3$ square is said to be trivial if it contains repeated entries; there apparently is known just one non-trivial magic square (together with its symmetries) with seven square entries:

\[
\begin{bmatrix}
373^2 & 289^2 & 565^2 \\
360721 & 425^2 & 23^2 \\
205^2 & 527^2 & 222121
\end{bmatrix}
\]

and no examples known of non-trivial squares with eight square entries, unless one extends the ground field when there are examples such as:

\[
\begin{bmatrix}
(22 + 4\sqrt{3})^2 & (17 - 9\sqrt{3})^2 & (5 + 13\sqrt{3})^2 \\
(23 - \sqrt{3})^2 & 2^2 \cdot 7 \cdot 19 & (23 + \sqrt{3})^2 \\
(5 - 13\sqrt{3})^2 & (17 + 9\sqrt{3})^2 & (22 - 4\sqrt{3})^2
\end{bmatrix}
\]

over the field $\mathbb{Q}(\sqrt{3})$.

Demanding that six given entries be square turns out to be equivalent to studying the intersection of three quadrics in five-dimensional projective space. By studying this surface in each of the sixteen ways (up to symmetry) of selecting six entries from a $3 \times 3$ square, we show that for each of these sixteen configurations there are infinitely many magic squares with the

six entries being perfect squares. This is done by parametrizations in one variable, so that asking for a seventh entry to be square in these examples involves finding rational points on hyperelliptic curves (in general of high genus) of type \( f(t) = \square \). But we have been unable to find any magic squares with seven square entries, other than the example at (1).

We further investigate in detail the geometry underlying one of the sixteen configurations; and this allows construction of an infinite family of eight-square magic squares over \( \mathbb{Q}(\sqrt{3}) \), such as (2).

1. Any three-by-three magic square of rational numbers has the form

\[
\begin{bmatrix}
  a + c & -a - b + c & b + c \\
 -a + b + c & c & a - b + c \\
 -b + c & a + b + c & -a + c
\end{bmatrix}
\]

with \( a, b, c \in \mathbb{Q} \). (In all that follows, a “magic square” will refer to a square with rational entries, unless specifically otherwise indicated.) The square (3) is trivial (has repeated entries) precisely when

\[
ab(a^2 - b^2)(a^2 - 4b^2)(4a^2 - b^2) = 0.
\]

Up to symmetry (rotation and reflection), there are precisely sixteen ways of selecting six entries from a \( 3 \times 3 \) square. These are as follows:

For each of these sixteen configurations, it is possible to find magic squares with the six selected entries perfect squares: see Figure 1 (where we list examples which are believed in each case to have minimum “magic” sum). We shall show that it is possible to find infinitely many parametrized examples of such squares in each of the sixteen cases I, \ldots, XVI. Originally, it was hoped that squares with seven square entries might be found by extending a square with six square entries; but of all the examples considered, and after considerable computing, only the square at (1) arose. (It is worth noting that Martin Gardner [6] has offered $100 for an example of a non-trivial nine square entry magic square, or a proof of non-existence of such.) Duncan Buell [5] has shown by careful search that there is no seven-square
magic square corresponding to the “hour-glass” configuration

\[
\begin{array}{ccc}
\hline
\hline
\hline
\end{array}
\]

in which the central element of the square is less than \(25 \cdot 10^{24}\).

The demand that each entry at (3) be a perfect square results in nine equations, which, on eliminating \(a, b, c\), is equivalent to the intersection of six quadrics in eight-dimensional projective space, a surface. It seems difficult to deduce properties of this surface of high degree. Recall the notorious problem of finding a cubical box with all edges, face diagonals and box diagonal rational: the corresponding equations are four quadrics in six-dimensional projective space. Here, we restrict to considering just six entries from (3) being squares. On eliminating \(a, b, c\) there now results the intersection of three quadrics in \(\mathbb{P}^5\), and there is some hope of applying to this surface elementary ideas from geometry. In particular, if the surface is non-singular, then it is \(K3\) and the methods of Swinnerton-Dyer [16] may be of aid.

2. The arithmetic techniques used to analyze each of the sixteen configurations are similar, and so detailed attention will be restricted to just a few cases.

Consider the configuration II, in which

\[\pm b + c = \square, \quad \pm a \pm b + c = \square.\]

Put

\[a \pm b + c = (g \pm h)^2, \quad -a \pm b + c = (r \pm s)^2, \quad \pm b + c = (m \pm n)^2,\]

so that

\[a = \frac{1}{2}(g^2 + h^2 - r^2 - s^2), \quad b/2 = gh = mn = rs, \quad c = m^2 + n^2 = \frac{1}{2}(g^2 + h^2 + r^2 + s^2).\]

From \(g/m = n/h = \beta/\gamma\), say, follows \(g = \alpha \beta, m = \alpha \gamma, n = \beta \delta, h = \gamma \delta\) with

\[a = (\alpha^2 - \delta^2)(\beta^2 - \gamma^2), \quad b = 2\alpha \beta \gamma \delta, \quad c = \alpha^2 \gamma^2 + \beta^2 \delta^2\]

and

\[
\begin{align*}
\alpha^2(-\beta^2 + 2\gamma^2) + 2\alpha \beta \gamma \delta + \delta^2(2\beta^2 - \gamma^2) &= (r + s)^2, \\
\alpha^2(-\beta^2 + 2\gamma^2) - 2\alpha \beta \gamma \delta + \delta^2(2\beta^2 - \gamma^2) &= (r - s)^2,
\end{align*}
\]

that is,

\[
\begin{align*}
E : \quad \left\{ \begin{array}{l}
\alpha^2(2 - \lambda^2) + 2\lambda \alpha \delta - \delta^2(1 - 2\lambda^2) = (\varrho + \sigma)^2, \\
\alpha^2(2 - \lambda^2) - 2\lambda \alpha \delta - \delta^2(1 - 2\lambda^2) = (\varrho - \sigma)^2,
\end{array} \right.
\end{align*}
\]

where we have put \(\lambda = \beta/\gamma, \varrho = r/\gamma, \sigma = s/\gamma\). Regarded as the intersection of two quadrics in \(\alpha, \delta, \varrho, \sigma\)-space over \(\mathbb{Q}(\lambda)\), \(E\) represents an elliptic curve.

Fig. 1 [cont.]
with distinguished point \((\alpha, \delta, \varrho, \sigma) = (1, 1, \lambda, 1)\). A cubic equation for the curve is given by

\[
E : \quad T^2 = S(S^2 - 4(1 - 3\lambda^2 + \lambda^4)S + 4(1 - \lambda^2)^4),
\]

and it is straightforward to verify that \((2(1-\lambda^2)^2, 4\lambda(1-\lambda^2)^2)\) is of order 4 in \(G = E(\mathbb{Q}(\lambda))\), with the torsion subgroup isomorphic to \(\mathbb{Z}/4\mathbb{Z}\); and the rank of \(E\) over \(\mathbb{Q}(\lambda)\) is equal to 1. The point \((2(1+\lambda)^4, 12\lambda(1+\lambda)^4)\) is of infinite order in \(G\), and likely a generator of the infinite component of \(G\), though this has not been confirmed. On (5) this point corresponds to \(P = (1, 1, 1, \lambda)\). The multiples of \(P\) on (5) give rise to points \((\alpha, \delta, \varrho, \sigma)\) which in turn give rise to \(a, b, c\) and corresponding magic squares for the configuration II. For example, \(-P\) is equal to

\[
((-5+\lambda^2)(1+7\lambda^2), (1-5\lambda^2)(7+\lambda^2), (1-5\lambda^2)(1+7\lambda^2), \lambda(-5+\lambda^2)(7+\lambda^2))
\]

with

\[
\begin{align*}
a &= 24(1 - \lambda^2)^2(1 + \lambda^2)(1 - 6\lambda + \lambda^2)(1 + 6\lambda + \lambda^2), \\
b &= -2\lambda(5 - \lambda^2)(1 - 5\lambda^2)(1 + 7\lambda^2)(7 + \lambda^2), \\
c &= (1 + \lambda^2)(5 - 6\lambda + 5\lambda^2)(5 + 6\lambda + 5\lambda^2)(1 + 14\lambda^2 + \lambda^4);
\end{align*}
\]

and the corresponding square \((m_{ij})\) is

\[(6)
\]

where the diagonal entries are

\[
\begin{align*}
m_{11} &= 49 - 451\lambda^2 + 1426\lambda^4 + 1426\lambda^6 - 451\lambda^8 + 49\lambda^{10}, \\
m_{22} &= 25 + 389\lambda^2 + 610\lambda^4 + 610\lambda^6 + 389\lambda^8 + 25\lambda^{10}, \\
m_{33} &= 1 + 1229\lambda^2 - 206\lambda^4 - 206\lambda^6 + 1229\lambda^8 + \lambda^{10}.
\end{align*}
\]

The magic squares that arise in this way from points \(Q\) and \(Q+T\) in \(G\) for \(T\) torsion, are symmetries of each other; to compute all magic squares arising from \(E\) it is only necessary therefore to consider points \(Q = mP\). One can even restrict to \(m > 0\); \(P\) produces a trivial square, \(2P\) produces (up to symmetry) the square at (6) with entries of degree 10, and \(3P\) produces a square with entries of degree 26.

It is possible to achieve a square with entries of degree 8 by means of the following specialization. Put

\[
(\beta, \gamma) = (1 + 2\mu + 3\mu^2, 2\mu).
\]
Then (4) takes the form
\[
\alpha^2(-1 - 4\mu - 2\mu^2 - 12\mu^3 - 9\mu^4) + 4\mu(1 + 2\mu + 3\mu^2)\alpha\delta
+ 2\delta^2(1 + 4\mu + 8\mu^2 + 12\mu^3 + 9\mu^4) = (r + s)^2, \\
\alpha^2(-1 - 4\mu - 2\mu^2 - 12\mu^3 - 9\mu^4) - 4\mu(1 + 2\mu + 3\mu^2)\alpha\delta
+ 2\delta^2(1 + 4\mu + 8\mu^2 + 12\mu^3 + 9\mu^4) = (r - s)^2,
\]
with point at \((\alpha, \delta) = (-1 + 3\mu^2, 1 - 2\mu + 3\mu^2)\). This leads to the magic square
\[
(1 - 4\mu - 4\mu^2 - 9\mu^4)^2 \quad (1 + 2\mu + 2\mu^2 - 6\mu^3 + 9\mu^4)^2 \quad (1 + 4\mu^2 - 12\mu^3 - 9\mu^4)^2
\]
where the diagonal entries are
\[
m_{11} = 1 + 4\mu + 8\mu^2 - 28\mu^3 - 2\mu^4 - 84\mu^5 + 72\mu^6 + 108\mu^7 + 81\mu^8, \\
m_{22} = (1 + \mu^2)(1 + 9\mu^2)(1 - 2\mu^2 + 9\mu^4), \\
m_{33} = 1 - 4\mu + 8\mu^2 + 28\mu^3 - 2\mu^4 + 84\mu^5 + 72\mu^6 - 108\mu^7 + 81\mu^8. 
\]
The curve at (8) has rank 2 over \(\mathbb{Q}(\mu)\) with independent points of infinite order given by
\[
(1, 1, 1 + 4\mu + 3\mu^2, -1 - 3\mu^2), \\
(-1 + 3\mu^2, 1 - 2\mu + 3\mu^2, 1 - 4\mu - 4\mu^2 - 9\mu^4, 1 + 4\mu^2 + 12\mu^3 + 9\mu^4)
\]
(\(1 + X\))(1 + 9\(X\))(1 - 2\(X\) + 9\(X^2\)) = \(\square\) has rational points with \(X = \mu^2\). But this elliptic curve of conductor 48 has rank 0, forcing \(\mu = 0\) and a consequent trivial square. For \(m_{11}\) or \(m_{33}\) to be square, the condition is that the curve of genus 3 given by \(1 + 4x + 8x^2 - 28x^3 - 2x^4 - 84x^5 + 72x^6 + 108x^7 + 81x^8 = \square\) have rational points. The curve does of course have only finitely many rational points; it seems likely that \(x = 0, \infty\) are the only such, though we are unable to show this. The curve contains in its Jacobian the elliptic curve \(U^4 + 4U^3 - 4U^2 - 64U - 32 = \square\) (observe the transformation \(U = 3x + 1/x\)), of conductor 1104 and rank 1, with \((-2, 8)\) a generator for the rational points. But computing the “small” rational points on this curve led to no non-trivial rational points on the curve of genus 3.

Each of the sixteen configurations I–XVI may be treated as in the above example for Category II. In each case it is straightforward to determine an elliptic fibration of the associated surface intersection of the three quadratic
forms. To shorten the labour, observe that there is a correspondence between squares of type II and squares of type XIII, namely

\[
\begin{array}{ccc}
m_{11} & B & C \\
D & m_{22} & F \\
G & H & m_{33}
\end{array}
\quad \leftrightarrow \quad
\begin{array}{ccc}
n_{11} & D & F \\
H & G & n_{23} \\
B & n_{32} & C
\end{array}
\]

with

\[
m_{11} = (F + H)/2, \quad n_{11} = B - D + G,
m_{22} = (C + G)/2, \quad n_{23} = B + F - H,
m_{33} = (B + D)/2, \quad n_{32} = F + G - C.
\]

Similarly, there is a correspondence between squares of type VII and XIV:

\[
\begin{array}{ccc}
m_{11} & m_{12} & C \\
D & E & F \\
G & m_{32} & I
\end{array}
\quad \leftrightarrow \quad
\begin{array}{ccc}
D & n_{12} & C \\
n_{21} & E & I \\
G & n_{32} & F
\end{array}
\]

with

\[
m_{11} = E + F - G, \quad n_{12} = -D + F + I,
m_{12} = -C + D + G, \quad n_{21} = C - E + F,
m_{32} = C + F - G, \quad n_{32} = C - G + I.
\]

It can also be noted that squares in Category VII occur in pairs:

\[
\begin{array}{ccc}
\cdot & \cdot & C \\
D & E & F \\
G & \cdot & I
\end{array}
\quad \leftrightarrow \quad
\begin{array}{ccc}
\cdot & \cdot & F \\
G & E & C \\
D & \cdot & I
\end{array}
\]

as do squares in Category XIII:

\[
\begin{array}{ccc}
\cdot & B & C \\
D & E & \cdot \\
G & \cdot & I
\end{array}
\quad \leftrightarrow \quad
\begin{array}{ccc}
\cdot & G & D \\
C & I & \cdot \\
B & \cdot & E
\end{array}
\]

We find in this manner parametrizations for the squares in Categories I–XVI of respective degrees 12, 8, 12, 12, 20, 12, 12, 20, 12, 20, 12, 20, 12, 20, 12, 20, 12 (but do not claim in any particular Category to have found the parametrization of smallest degree). For reasons of space, these parametrizations are not listed here, but are available to interested parties from the author.
Finally we consider one further example, squares of type VII. Here
\[ \pm b + c = \Box, \quad \pm (a - b) + c = \Box, \quad -a + c = \Box, \quad c = \Box \]
and putting
\[ c = m^2 + n^2 = r^2 + s^2 = u^2, \quad b = 2mn, \quad a - b = 2rs, \quad a = u^2 - v^2, \]
we have
\[ m^2 + n^2 = r^2 + s^2 = u^2, \quad u^2 - v^2 = 2mn + 2rs. \]
With
\[ m = \alpha \beta + \gamma \delta, \quad n = \alpha \gamma - \beta \delta, \quad r = \alpha \gamma + \beta \delta, \quad s = \alpha \beta - \gamma \delta \]
we obtain
\[ (\alpha^2 + \delta^2)(\beta^2 + \gamma^2) = u^2, \]
\[ \alpha^2(\beta^2 - 4\beta \gamma + \gamma^2) + \delta^2(\beta^2 + 4\beta \gamma + \gamma^2) = v^2, \]
that is,
\[ (11) \quad F : \begin{cases} (\alpha^2 + \delta^2)(1 + \lambda^2) = \varrho^2, \\ \alpha^2(1 - 4\lambda + \lambda^2) + \delta^2(1 + 4\lambda + \lambda^2) = \sigma^2, \end{cases} \]
where we have put \( \lambda = \beta / \gamma, \varrho = u / \gamma, \sigma = v / \gamma \). As a curve in \( \alpha, \delta, \varrho, \sigma \)-space over \( \mathbb{Q}(\lambda) \), (11) is an elliptic curve with distinguished point \((\alpha, \delta, \varrho, \sigma) = (\lambda, 1, 1 + \lambda^2, 1 + 2\lambda - \lambda^2)\). The \( \mathbb{Q}(\lambda) \)-rank turns out to equal 2, with independent points of infinite order \( R = (1, \lambda, 1 + \lambda^2, 1 - 2\lambda - \lambda^2), S = (1, -\lambda, 1 + \lambda^2, 1 - 2\lambda - \lambda^2) \). Then \(-S\) has
\[ (\alpha, \delta) = (1 + 4\lambda + 2\lambda^2 + 4\lambda^3 - 3\lambda^4, \lambda(3 + 4\lambda - 2\lambda^2 + 4\lambda^3 - \lambda^4)) \]
leading to the square
\[
\begin{bmatrix}
  * & * & (1 + \lambda^2)^2(1 + 8\lambda + 6\lambda^2 - 8\lambda^3 + \lambda^4)^2 \\
  (1 + 6\lambda + 5\lambda^2 + 4\lambda^3 - 5\lambda^4 + 6\lambda^5 - \lambda^6)^2 & (1 + \lambda^2)^2(1 + 4\lambda + 6\lambda^2 - 4\lambda^3 + \lambda^4)^2 & (1 + 2\lambda - \lambda^2)^2(1 + 6\lambda^2 + \lambda^4)^2 \\
  (1 + \lambda^2)^2(1 - 10\lambda^2 + \lambda^4)^2 & * & (1 + 2\lambda - 3\lambda^2 + 12\lambda^3 + 3\lambda^4 + 2\lambda^5 - \lambda^6)^2
\end{bmatrix}
\]
where the non-square entries are
\[
m_{11} = (1 + 2\lambda - \lambda^2)(1 + 10\lambda + 43\lambda^2 + 24\lambda^3 + 58\lambda^4 + 60\lambda^5 - 58\lambda^6 + 24\lambda^7 - 43\lambda^8 + 10\lambda^9 - \lambda^{10}),
m_{12} = (1 - 10\lambda + 5\lambda^2 - 12\lambda^3 - 5\lambda^4 + 6\lambda^5 - \lambda^6) \times (1 + 6\lambda + 5\lambda^2 - 12\lambda^3 - 5\lambda^4 - 10\lambda^5 - \lambda^6),
m_{32} = (1 + 2\lambda - \lambda^2)(1 + 18\lambda + 75\lambda^2 + 24\lambda^3 + 90\lambda^4 + 44\lambda^5 - 90\lambda^6 + 24\lambda^7 - 75\lambda^8 + 18\lambda^9 - \lambda^{10}).
\]
Computing “small” combinations of \( R, S \) on \( F \) leads to squares with entries of degree 12, 20, 28, \ldots
The first equation at (11) may be parametrized by
\[ \alpha : \delta : \varrho = \lambda(p^2 - q^2) + 2pq : (p^2 - q^2) - 2\lambda pq : (\lambda^2 + 1)(p^2 + q^2) \]
and then the second equation at (11) demands
\[
(12) \quad (1 + 2\lambda - \lambda^2)^2p^4 - 32\lambda^2p^3q + 2(1 - 12\lambda + 2\lambda^2 + 12\lambda^3 + \lambda^4)p^2q^2 + 32\lambda^2pq^3 \\
+ (1 + 2\lambda - \lambda^2)^2q^4 = 0.
\]
The conditions that the remaining three entries in this Category VII square be perfect squares have become:
\[
(13) \quad (1 + 2\lambda - \lambda^2)^2p^4 - 4(1 + 10\lambda^2 + \lambda^4)p^3q + 2(1 - 12\lambda + 2\lambda^2 + 12\lambda^3 + \lambda^4)p^2q^2 \\
+ 4(1 + 10\lambda^2 + \lambda^4)pq^3 + (1 + 2\lambda - \lambda^2)^2q^4 = 0,
\]
\[
(1 - 2\lambda - \lambda^2)^2p^4 + 4(1 + 10\lambda^2 + \lambda^4)p^3q + 2(1 + 12\lambda + 2\lambda^2 - 12\lambda^3 + \lambda^4)p^2q^2 \\
- 4(1 + 10\lambda^2 + \lambda^4)pq^3 + (1 - 2\lambda - \lambda^2)^2q^4 = 0.
\]
In order to try and find a seven-square magic square, (12) was searched for solutions also satisfying at least one of the equations (13). The only solution (up to symmetry) occurred at \( \lambda = 13 \) with \( (p, q) = (9, 2) \), giving rise to the square at (1). (By symmetry considerations, it is sufficient to search over a region in which \( p, q, \) and \( n(\lambda) = \text{numerator}(\lambda), d(\lambda) = \text{denominator}(\lambda) \) are positive; the search covered the region \( p + q + n(\lambda) + d(\lambda) \leq 1000. \))

3. We use geometric techniques to analyze squares in Category III. Here,
\[ \pm a + c = 0, \quad \pm b + c = 0, \quad \pm(a + b) + c = 0, \]
and putting
\[ a = 2TU, \quad b = 2VW, \quad a + b = -2XY, \quad c = T^2 + U^2 = V^2 + W^2 = X^2 + Y^2 \]
there results
\[ S : \quad T^2 + U^2 = V^2 + W^2 = X^2 + Y^2, \quad TU + VW + XY = 0. \]
This intersection of three quadrics in \( \mathbb{P}^5 \) is the equation of a surface. It is readily determined to be non-singular, and so \( S \) is K3. There is a large symmetry group on \( S \), with the obvious symmetries \( (TU) \leftrightarrow (UT) \), etc., \( (TUVW) \leftrightarrow (VWTU) \), etc., \( (TUVWXY) \leftrightarrow (VWXYTU) \), etc., and sign-changes \( (TVX) \leftrightarrow (-T - V - X) \), etc., generating a group of order 384. There are 24 conics on \( S \), four lying in each of the six hyperplanes \( T = 0, U = 0, \ldots, Y = 0 \), and typified by \( \{T = X, U = -Y, V = 0, W^2 = X^2 + Y^2\} \), which will be denoted by \( C_{TXV} \), where \( C_{rst} \) denotes the conic with \( r = s, t = 0 \). \( S \) also contains the 8 complex conics \( \{T = \varepsilon_1 U, V = \varepsilon_2 W, X = \varepsilon_3 Y, \varepsilon_1 U^2 + \varepsilon_2 W^2 + \varepsilon_3 Y^2 = 0\} \) where \( \varepsilon_i \) are square roots of \(-1\). We denote these conics by \( C_{j_1j_2j_3} \) with \( j_k = +, - \) according as \( \varepsilon_k = i, -i \).
There are also 32 straight lines on \( S \), typified up to symmetry by the following equations:

\[
L_1 : \{ T + X = V, T - X = -\sqrt{3} W, U + Y = W, U - Y = \sqrt{3} V \}
\]

with parametrization

\[
(T, U, V, W, X, Y) = (\sqrt{3} \alpha, \alpha + 2 \beta, \sqrt{3} (\alpha + \beta), -\alpha + \beta, \sqrt{3} \beta, -2 \alpha - \beta).
\]

Consider now the intersection of \( S \) with the hyperplane

\[
U - Y = \lambda (X + T).
\]

This cuts out on \( S \) the quadrics \( C_{UYV} \) and \( C_{UYW} \), together with a residual intersection of degree 4, on which

\[
U + Y = \frac{1}{\lambda} (X - T),
\]

and

\[
\mathcal{E}_\lambda : \begin{cases} 
(1 + 2 \lambda - \lambda^2)^2 T^2 - 2(1 - \lambda^4) T X + (1 - 2 \lambda - \lambda^2)^2 X^2 = 4 \lambda^2 (V + W)^2, \\
(1 - 2 \lambda - \lambda^2)^2 T^2 - 2(1 - \lambda^4) T X + (1 + 2 \lambda - \lambda^2)^2 X^2 = 4 \lambda^2 (V - W)^2.
\end{cases}
\]

As the intersection of two quadrics in \( \mathbb{P}^3 \) with distinguished point

\[
\mathcal{O}_\lambda(T, X, V, W) = (2 \lambda, 0, 1 - \lambda^2, 2 \lambda),
\]

\( \mathcal{E}_\lambda \) represents the equation of an elliptic curve over \( \mathbb{C}(\lambda) \). The curve is singular precisely at \( \lambda = \pm 1, \pm i, \pm \sqrt{3}, \pm 1/\sqrt{3} \).

At \( \lambda = 1 \), \( \mathcal{E}_\lambda \) decomposes as the sum

\[
\mathcal{E}_1 : C_{UXV} + C_{UXW}.
\]

Similarly,

\[
\mathcal{E}_{-1} : C_{TYV} + C_{TYW}.
\]

When \( \lambda = i \), then \( \mathcal{E}_\lambda \) splits as the two conics:

\[
\mathcal{E}_i : C_{-++} + C_{-+-}
\]

with conjugate decomposition at \( \lambda = -i \),

\[
\mathcal{E}_{-i} : C_{++-} + C_{+-+}.
\]

When \( \lambda = \sqrt{3} \), then \( \mathcal{E}_\lambda \) splits as the four lines:

\[
\mathcal{E}_{\sqrt{3}} : \{ T + X = V, T - X = -\sqrt{3} W, U + Y = W, U - Y = \sqrt{3} V \}
\]

\[
+ \{ T + X = W, T - X = -\sqrt{3} V, U + Y = V, U - Y = \sqrt{3} W \}
\]

\[
+ \{ T + X = -W, T - X = \sqrt{3} V, U + Y = -V, U - Y = -\sqrt{3} W \}
\]

\[
+ \{ T + X = -V, T - X = \sqrt{3} W, U + Y = -W, U - Y = -\sqrt{3} V \}
\]

with conjugate decomposition at \( \lambda = -\sqrt{3} \); and at \( \lambda = 1/\sqrt{3} \), the decomposition is again four lines corresponding to the symmetry of \( S \) obtained by changing the signs of \( U, W, X \).
A cubic model for $E_\lambda$ is given by
\begin{equation}
\tau^2 = \sigma(\sigma + (3 - \lambda^2)^2)(\sigma + (1 - 3\lambda^2)^2).
\end{equation}

The torsion group of $E_\lambda$ over $\mathbb{C}(\lambda)$ is isomorphic to $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ generated by $T_4(\sigma, \tau) = (-(3 - \lambda^2)(1 - 3\lambda^2), -2(1 + \lambda^2)(3 - \lambda^2)(1 - 3\lambda^2))$ of order 4, and $T_2(\sigma, \tau) = (-(3 - \lambda^2)^2, 0)$ of order 2. These correspond to
\begin{align*}
T_4(T, X, V, W) &= (1 - \lambda^2, 1 + \lambda^2, 1 - \lambda^2, -2\lambda), \\
T_2(T, X, V, W) &= (1 + \lambda^2, 1 - \lambda^2, 2\lambda, 1 - \lambda^2).
\end{align*}

The four singular fibres of $E_\lambda$ at $\lambda = \pm 1, \pm i$ are each of Kodaira Type $I_2$, and of Type $I_4$ at $\lambda = \pm \sqrt{3}, \pm 1/\sqrt{3}$. Denote the Néron–Severi group of the surface $\mathcal{S}$ over $\mathbb{C}$ by $\text{NS}(\mathcal{S}, \mathbb{C})$. Then $\text{NS}(\mathcal{S}, \mathbb{C})$ is a finitely generated $\mathbb{Z}$-module, and it follows from Shioda [13] that
\begin{equation*}
\text{rank } \text{NS}(\mathcal{S}, \mathbb{C}) = \text{rank } E_\lambda(\mathbb{C}(\lambda)) + 2 + 4 \cdot (2 - 1) + 4 \cdot (4 - 1).
\end{equation*}

Since the rank of the Néron–Severi group of a $K3$-surface cannot exceed 20 (see for example Barth et al. [1]), we have rank $E_\lambda(\mathbb{C}(\lambda)) \leq 2$. Two independent points of infinite order are readily found on $E_\lambda$, namely
\begin{align*}
P_1(T, X, V, W) &= (1 - \lambda^2, 1 + \lambda^2, 2\lambda, -1 + \lambda^2), \\
P_2(T, X, V, W) &= (2 - \sqrt{3} + \lambda, 2 - \sqrt{3} - \lambda, (1 - \sqrt{3})(1 + \lambda), (1 - \sqrt{3})(1 - \lambda))
\end{align*}
and thus rank $E_\lambda(\mathbb{C}(\lambda)) = 2$.

Lemma. $E_\lambda(\mathbb{C}(\lambda)) \simeq \mathbb{Z} \times \mathbb{Z} \times \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, with respective generators $P_1, P_2, T_4, T_2$.

Proof. $P_1, P_2$ correspond respectively to the points
\begin{align*}
P_1(\sigma, \tau) &= (-(1 + \lambda^2)^2, -8\lambda(1 - \lambda^4)), \\
P_2(\sigma, \tau) &= ((2 + \sqrt{3})(1 - \sqrt{3}\lambda)(\sqrt{3} + \lambda)(2 - \sqrt{3} - \lambda)^2, \\
&-2(1 + \sqrt{3})(1 - \lambda)(1 - \sqrt{3}\lambda)(\sqrt{3} + \lambda)(2 - \sqrt{3} - \lambda)(1 + \lambda^2))
\end{align*}
on (21), and it is now straightforward to compute canonical heights by the formulae of Silverman [14]. There results $\hat{h}(P_1) = 1$ and $\hat{h}(P_2) = 1/2$, $\hat{h}(P_1 + P_2) = 1/2$. The canonical height pairing is defined by
\begin{equation*}
\langle P, Q \rangle = \frac{1}{2} (\hat{h}(P + Q) - \hat{h}(P) - \hat{h}(Q))
\end{equation*}
and so the height pairing matrix $((\langle P_i, P_j \rangle)_{1 \leq i, j \leq 2})$ is equal to
\begin{equation*}
\mathcal{H} = \begin{pmatrix}
1 & -1/2 \\
-1/2 & 1/2
\end{pmatrix}
\end{equation*}
with $\det(\mathcal{H}) = 1/4$. Thus $P_1, P_2$ are independent, and by a theorem of Kuwata [8], $P_1, P_2$ generate a subgroup of index at most a power of 2 in $E_\lambda(\mathbb{C}(\lambda))$ modulo torsion. It is not difficult to show directly that $P_1 + T$,
$P_2 + T$, $P_1 + P_2 + T$ cannot lie in $2E_\lambda(\mathbb{C}(\lambda))$ for any torsion element $T$, and thus $P_1$, $P_2$ generate $E_\lambda(\mathbb{C}(\lambda))$ modulo torsion, as required.

To find a set of generators for $NS(S, \mathbb{C})$ over $\mathbb{Z}$, we use ideas of Swinnerton-Dyer [16], to which article the reader is referred for full details (see also Bremner [2], [4]) for further applications of these methods). The group $NS(S, \mathbb{C})$ is spanned over $\mathbb{Z}$ by

1. the locus of the point $O_\lambda$,
2. the components of the singular fibres in the pencil $E_\lambda$,
3. the loci of the generators $P_1$, $P_2$, $T_4$, $T_2$ of the group $E_\lambda(\mathbb{C}(\lambda))$.

Now the locus of $O_\lambda$ as $\lambda$ varies is the conic $C_{TWX}$; the locus of $P_1$ is the conic $C_{UVY}$; and the locus of $P_2$ is the straight line

$L_2: \{V - X = U, V + X = -\sqrt{3}T, W - Y = T, W + Y = \sqrt{3}U\}$.

From (22), the loci of $T_4$, $T_2$ are the conics $C_{TVY}$ and $C_{WXU}$ respectively. Together with the components of the singular fibres of $E_\lambda$, from (16)–(20), the following divisors therefore generate $NS(S, \mathbb{C})$ over $\mathbb{Z}$:

\begin{equation}
(23) \quad C_{TVY}, C_{TWX}, C_{TVY}, C_{TVY}, C_{UVY}, C_{UXV}, C_{UXW}, C_{WXU},
\end{equation}

$C_{+++}, C_{+--}, C_{---}, C_{--} + L_2$; the 4 lines at (20) (with symmetries).

The intersection matrix of these 29 divisors is straightforward to write down, and as expected, has rank 20. By repeatedly discarding a divisor that is a $\mathbb{Z}$-linear combination of remaining divisors, the following result is obtained.

**THEOREM.** The following 20 divisors generate $NS(S, \mathbb{C})$ over $\mathbb{Z}$: $C_{TVX}, C_{UVX}, C_{TWX}, C_{TVY}, C_{TVY}, C_{UXV}, C_{UXW}, C_{WXU}, C_{TXV}, C_{+++}, L_2$ (which we denote by $\Gamma_1, \ldots, \Gamma_{14}$, respectively), and the 6 lines:

\begin{equation}
(24) \quad \begin{align*}
\Gamma_{15}: \{T + X = V, & \quad T - X = \sqrt{3} W, \quad U + Y = W, \quad U - Y = \sqrt{3} V\}, \\
\Gamma_{16}: \{T + X = -V, & \quad T - X = \sqrt{3} W, \quad U + Y = -W, \quad U - Y = -\sqrt{3} V\}, \\
\Gamma_{17}: \{T + X = W, & \quad T - X = -\sqrt{3} V, \quad U + Y = V, \quad U - Y = \sqrt{3} W\}, \\
\Gamma_{18}: \{T + X = \sqrt{3} W, & \quad T - X = V, \quad U + Y = -\sqrt{3} V, \quad U - Y = W\}, \\
\Gamma_{19}: \{T + X = -\sqrt{3} W, & \quad T - X = -V, \quad U + Y = \sqrt{3} V, \quad U - Y = -W\}, \\
\Gamma_{20}: \{T + X = \sqrt{3} V, & \quad T - X = W, \quad U + Y = -\sqrt{3} W, \quad U - Y = V\}.
\end{align*}
\end{equation}

**COROLLARY.** Denote by $NS(S, \mathbb{Q})$ that subgroup of $NS(S, \mathbb{C})$ which is defined over $\mathbb{Q}$. Then $NS(S, \mathbb{Q})$ is generated over $\mathbb{Z}$ by the twelve divisors $\Gamma_1, \ldots, \Gamma_{12}$.

**COROLLARY.** Any rational curve on $S$ has even degree.

**REMARK.** This corollary is mildly inconvenient for the following reason. We are interested in obtaining one-parameter solutions of the equations for $S$, which geometrically represent irreducible curves of genus 0 lying on $S$. 

Squares of squares
But an irreducible curve of genus 0 of even degree may not in fact actually be rationally parametrizable.

To any curve $\Gamma$ defined over $\mathbb{Q}$ on $S$ there thus correspond uniquely determined integers $m_1, \ldots, m_{12}$ such that $\Gamma \sim m_1\Gamma_1 + \ldots + m_{12}\Gamma_{12}$. The genus of $\Gamma$ is a quadratic form in the $m_i$, given by

$$p_a(\Gamma) = \frac{1}{2}(\Gamma.\Gamma) + 1$$

where $(\Gamma.\Gamma)$ is the self-intersection number (see Shafarevich [12], p. 5). Following simple algebra, there results

$$\frac{1}{2} \text{deg}(\Gamma)^2 - 4(\Gamma.\Gamma) = (m_1 + m_2 - m_3 - m_4 - m_5 - m_6 + m_8 + m_9 + 2m_{10})^2 + (m_1 + m_2 - m_3 - m_4 - m_5 - m_6 + m_8 + m_9 + 2m_{11} - 2m_{12})^2 + 2(m_1 - m_4 + m_5 + m_6 - m_8 - m_9 + m_{10} + m_{11} - m_{12})^2 + 2(m_1 - m_4 - m_5 - m_6 - m_7 + m_8 + m_9 - m_{10} - m_{11} + m_{12})^2 + 4(m_1 - m_3)^2 + 3(m_2 - m_3)^2 + (m_2 - m_3 - 2m_7)^2 + 4(m_2 - m_4 + m_5)^2 + 4m_6^2 + 4(m_7 - m_8 + m_9)^2 + 2(m_{10} - m_{11} - m_{12})^2.$$

This is now in a form suitable for machine computation. Given the degree and self-intersection number of $\Gamma$, it is possible to tabulate the finitely many sets of integers $m_1, \ldots, m_{12}$ that are solutions of (25). In addition, since we are only interested in irreducible curves $\Gamma$, further restrictions are imposed on the $m_i$ by insisting that $\Gamma$ have non-negative intersection number with every known curve lying on the surface. In this manner, it is computed first that the only irreducible rational curves on $S$ of degree 2 are the known conics (which correspond to trivial squares), and second that there are no irreducible rational curves of degree 4. Of degree 6, there is the curve represented by the divisor $\Gamma_4 + \Gamma_5 + \Gamma_8 + \Gamma_9 - \Gamma_{12}$, together with 96 symmetries. This sextic is parametrized as follows:

$$T : U : V : W : X : Y = \frac{2\lambda(7 + 4\lambda - \lambda^2)(1 + 2\lambda - 3\lambda^2 + 2\lambda^3)}{(1 - \lambda)(5 + 8\lambda + \lambda^2)(1 + \lambda + 5\lambda^2 - 3\lambda^3)} : -4(1 + 2\lambda - \lambda^2)(1 - 2\lambda - \lambda^2)^2 : 3(1 + \lambda^2)(1 + 8\lambda + 2\lambda^2 - 8\lambda^3 + \lambda^4) : 2(1 + 4\lambda - 7\lambda^2)(2 + 3\lambda + 2\lambda^2 - \lambda^3) : (1 + \lambda)(1 - 8\lambda + 5\lambda^2)(3 + 5\lambda - \lambda^2 + \lambda^3),$$

and leads to the square with entries

$$m_{11} = (5 + 22\lambda + 57\lambda^2 - 36\lambda^3 - 45\lambda^4 + 38\lambda^5 - \lambda^6)^2,$$
\[ m_{12} = (1 - 2\lambda - \lambda^2)^2(7 + 20\lambda + 2\lambda^2 + 4\lambda^3 - 5\lambda^4)^2, \]
\[ m_{13} = (1 - 32\lambda - 37\lambda^2 + 48\lambda^3 + 19\lambda^4 + 16\lambda^5 - 7\lambda^6)^2, \]
\[ m_{31} = (7 + 16\lambda - 19\lambda^2 + 48\lambda^3 + 37\lambda^4 - 32\lambda^5 - \lambda^6)^2, \]
\[ m_{32} = (1 + 38\lambda + 45\lambda^2 - 36\lambda^3 - 57\lambda^4 + 22\lambda^5 - 5\lambda^6)^2, \]
\[ m_{33} = (1 - 2\lambda - \lambda^2)^2(5 + 4\lambda - 2\lambda^2 + 20\lambda^3 - 7\lambda^4)^2 \]

and middle row elements
\[ m_{21} = (1 - 2\lambda - \lambda^2)^2 \]
\[ \times (1 - 200\lambda - 436\lambda^2 + 232\lambda^3 + 94\lambda^4 - 88\lambda^5 + 860\lambda^6 - 520\lambda^7 + 73\lambda^8), \]
\[ m_{22} = (5 - 4\lambda + \lambda^2)(1 + 4\lambda + 5\lambda^2)(1 + 18\lambda^2 + \lambda^4)(5 - 6\lambda^2 + 5\lambda^4), \]
\[ m_{23} = (7 + 38\lambda - 9\lambda^2 - 36\lambda^3 + 57\lambda^4 + 22\lambda^5 - 23\lambda^6) \]
\[ \times (7 + 14\lambda + 15\lambda^2 + 108\lambda^3 - 87\lambda^4 - 2\lambda^5 + \lambda^6). \]

A search for values of \( \lambda \) making one of these latter three entries square disclosed only \( \lambda = \pm 1 \), giving trivial cases.

There are no irreducible rational curves of degree 8 on \( S \), and up to symmetry just one curve of degree 10, given by the divisor \( 2\Gamma_1 + 2\Gamma_3 + \Gamma_4 + \Gamma_6 - 2\Gamma_7 - \Gamma_8 + 2\Gamma_9 + \Gamma_{11} - \Gamma_{12} \) with parametrization
\[ T : U : V : W : X : Y = 2(-1+\lambda)(-2-6\lambda+\lambda^2)(-2+10\lambda-11\lambda^2+4\lambda^3)(100-216\lambda+128\lambda^2-36\lambda^3+\lambda^4) : (22-6\lambda+\lambda^2)(-8+18\lambda-14\lambda^2+3\lambda^3)(72-220\lambda+264\lambda^2-152\lambda^3+30\lambda^4+5\lambda^5) : (14-30\lambda+17\lambda^2)(-4+10\lambda-4\lambda^2+\lambda^3)(112-188\lambda+104\lambda^2-16\lambda^3-8\lambda^4+\lambda^5) : 2(10-18\lambda+7\lambda^2)(-6+4\lambda-3\lambda^2+\lambda^3)(92-264\lambda+304\lambda^2-156\lambda^3+23\lambda^4) : 3(2-2\lambda+\lambda^2)(20-40\lambda+24\lambda^2-4\lambda^3+\lambda^4)(68-264\lambda+280\lambda^2-84\lambda^3+5\lambda^4) : -8(-2+\lambda^2)(-4-6\lambda+\lambda^2)(-152+480\lambda-636\lambda^2+432\lambda^3-150\lambda^4+24\lambda^5+\lambda^6). \]

There are no irreducible rational curves of degree 12, and, up to symmetry, 6 of degree 14 corresponding to the divisors:
\[ \Gamma_3 - \Gamma_4 + 2\Gamma_5 + \Gamma_6 - \Gamma_7 + 2\Gamma_8 + 2\Gamma_{11} + \Gamma_{12}, \]
\[ \Gamma_3 - \Gamma_4 - \Gamma_5 + \Gamma_7 + \Gamma_8 + 3\Gamma_{10} + 3\Gamma_{12}, \]
\[ \Gamma_1 + 3\Gamma_2 + \Gamma_3 + \Gamma_4 - 2\Gamma_5 + 2\Gamma_6 + \Gamma_7 - \Gamma_8 + \Gamma_9, \]
\[ \Gamma_2 - \Gamma_5 + 3\Gamma_6 + 3\Gamma_9 + \Gamma_{11}, \]
\[ -2\Gamma_7 + 2\Gamma_9 + \Gamma_{10} + 3\Gamma_{11} + 3\Gamma_{12}, \]
\[ \Gamma_5 + \Gamma_7 - \Gamma_9 + 3\Gamma_{11} + 3\Gamma_{12}. \]

It becomes impracticable to compute the zeros of the form (25) for degrees greater than 14; and in any event, deciding whether the divisors found in this way represent irreducible curves becomes increasingly difficult. The manner in which we have resolved this for the divisors above is as follows.
As in Swinnerton-Dyer [16] it is most useful to introduce non-linear automorphisms of the surface.

Let $E$ denote a pencil of curves on $S$ of genus 1, the general member of which is irreducible; and let $C_1, C_2$ be two curves on $S$ each having precisely one point of intersection with any member of $E$. For $P$ a generic point of $S$, let $E_P$ be that member of $E$ which passes through $P$, and let $P_1, P_2$ be the points of $E_P$ in which $C_1, C_2$ intersect $E_P$. Then

$$P \mapsto P_1 + P_2 - P,$$

where the addition is that of the group law on $E_P$, defines a birational map of $S$ to itself. Such a map is necessarily biregular (Shafarevich [12], Chapter VII, Corollary to Theorem 1), and hence gives an automorphism of $S$. Moreover, it is clear from the definition that this automorphism is actually an involution. The involution certainly interchanges the curves $C_1, C_2$, and preserves each non-singular fibre of $E$, so by biregularity, actually preserves every fibre of $E$. So if the fibre is singular, then the involution permutes the components of the decomposition, in particular interchanging the component containing $P_1$ with the component containing $P_2$. Further information about the action on the Néron–Severi group is obtained from the fact that the involution has fixed points on each non-singular fibre (for there are just four points $P$ satisfying $2P = P_1 + P_2$), and hence, by specialization, at least one fixed point on every fibre. In general, the components of $E$ together with $C_1$ and $C_2$ span only a subgroup $G$ of the Néron–Severi group, so there is not yet sufficient information to determine fully the action of the involution. However, Bremner [2] shows that the involution actually must reverse every element of the orthogonal complement (with respect to intersection) of $G$ in the Néron–Severi group; and this in general now allows computation of the action of the involution. Indeed, the parametrizations of the curves of degrees 6 and 10 above were computed in exactly this way, as the image of a conic under an involution chosen with appropriate $C_1, C_2$.

As an example, we observe that up to symmetry there is on $S$ just one other elliptic pencil $F_\lambda$ besides $E_\lambda$ of degree 4 (put $\deg(\Gamma) = 4$ and $(\Gamma, \Gamma) = 0$ in (25)), with the divisor $\Gamma_1 + \Gamma_3$. It is the residual intersection of $S$ with the hyperplane

$$T - U + V + W = \lambda X;$$

after removing the conics $C_{UVX}, C_{UXW}$. $F_\lambda$ is singular at $\lambda = \pm 2\sqrt{2}, \pm 1/\sqrt{2}$ (nodal quartics), together with the following decompositions:

$$F_0 : \ C_{UVY} + C_{UWY}, \quad F_\infty : \ C_{TVX} + C_{TWX},$$
\[ \mathcal{F}_{1+\sqrt{3}}: \quad \{U - X = -\sqrt{3}W, U + X = V, \quad T - Y = \sqrt{3}V, \ T + Y = W\} \]
\[+ \{U - X = -\sqrt{3}V, U + X = W, \quad T - Y = \sqrt{3}W, T + Y = V\} \]
\[+ \{T - X = V, \quad T + X = \sqrt{3}W, U - Y = -W, \ U + Y = -\sqrt{3}V\} \]
\[+ \{T - X = -W, \quad T + X = \sqrt{3}V, U - Y = -V, \ U + Y = -\sqrt{3}W\} \]

with conjugate decomposition at \( \lambda = 1 - \sqrt{3} \), and symmetric decompositions at \( \lambda = -1 \pm \sqrt{3} \). Choosing \( C_1, C_2 \) as the conics \( C_{WXT}, C_{WYT} \) respectively, results in the following involution, where we represent the action by means of a 12 x 12 matrix on \( \Gamma_1, \ldots, \Gamma_{12} \) as basis:

\[
\phi:\begin{pmatrix}
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & -1 & 0 & -1 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 \\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & -1 & 0 & 1 & 1 & 0 & 1 & 0 & 1 \\
0 & 0 & 0 & -1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 1 \\
0 & -1 & 0 & -1 & 0 & 1 & 0 & 1 & 1 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & -1 & 0 & 0 & 0 \\
0 & -1 & 0 & 0 & 1 & 0 & -1 & 0 & 1 & 1 & 0 & 0 \\
1 & 0 & 1 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & -1 & 0 \\
0 & 1 & 0 & 0 & -1 & 0 & 1 & 0 & -1 & 0 & 0 & 1
\end{pmatrix}
\]

(so \( \phi(\Gamma_1) = \Gamma_3 \), etc.)

The image of the conic \( C_{TWY} \) (with divisor \( \Gamma_2 + \Gamma_4 - \Gamma_5 \)) is the sextic curve with divisor \(-\Gamma_2 + \Gamma_7 + \Gamma_8 + \Gamma_{10} + \Gamma_{12}\), whence the parametrization (26). Similarly, the sextic \( \Gamma_1 + \Gamma_4 + \Gamma_6 + \Gamma_8 - \Gamma_{11} \) maps under the involution to the divisor \(-\Gamma_1 - \Gamma_2 - \Gamma_4 - \Gamma_5 + \Gamma_6 + \Gamma_7 + \Gamma_8 + \Gamma_9 + 2\Gamma_{10} + \Gamma_{11} + 2\Gamma_{12} \) of degree 10, producing the parametrization at (27). The involution may also be useful in spotting reducibility of a divisor. For example, up to symmetry, just one divisor arises from (25) of degree 12 and self-intersection \(-2 \), namely
\[-\Gamma_2 + \Gamma_3 - \Gamma_4 + \Gamma_7 + \Gamma_8 + \Gamma_9 + 2\Gamma_{10} + 2\Gamma_{12} \]. However, under \( \phi \), this divisor maps to the sum of \( \Gamma_{10} \) and the line pair \( \{U - X = -V, U + X = \mp \sqrt{3}W, T - Y = -W, T + Y = \pm \sqrt{3}V\} \), and accordingly is reducible.

A theorem whose proof was sketched by E. Looijenga (see Sterk [15]) proves that all curves of genus 0 on \( S \) are obtainable by possibly repeated application of a finite set of automorphisms of the surface to one of a finite number of curves of genus 0 on the surface. Swinnerton-Dyer [16] proved such a theorem for the quartic \( K3 \) surface \( A^4 + B^4 = C^4 + D^4 \) with explicit determination of the automorphisms (two in number, together with the sym-
metries) and set of base curves comprising the straight line $A = C, B = D$. For an explicit such calculation on another quartic surface (contained in the four-fold $x^5 + y^5 + z^5 = u^5 + v^5 + w^5$), see Bremner [4]. In similar manner it should be possible, in principle at least, to construct the relevant sets of automorphisms and base curves for the surface $S$. In practice however, the computation is sufficiently daunting that it has not been pursued. (We remark that at least two further automorphisms of $S$ seem to be needed in order to generate the six curves of degree 14.)

4. We turn finally to a brief investigation over the ground field $\mathbb{Q}(\sqrt{3})$. The line at (14) corresponds to the square

$$((1 + \sqrt{3})\alpha + 2\beta)^2 \quad (2\alpha + (1 - \sqrt{3})\beta)^2 \quad ((1 - \sqrt{3})\alpha - (1 + \sqrt{3})\beta)^2$$

$$((1 + \sqrt{3})\alpha - (1 - \sqrt{3})\beta)^2 \quad (2\alpha + (1 + \sqrt{3})\beta)^2 \quad ((1 - \sqrt{3})\alpha + 2\beta)^2$$

where the middle row elements are

$$m_{21} = 4(1 - \sqrt{3})\alpha^2 + 4(1 - \sqrt{3})\alpha\beta + (1 + \sqrt{3})^2\beta^2,$$

$$m_{22} = 4\alpha^2 + 4\alpha\beta + 4\beta^2,$$

$$m_{23} = 4(1 + \sqrt{3})\alpha^2 + 4(1 + \sqrt{3})\alpha\beta + (1 - \sqrt{3})^2\beta^2.$$

To achieve two of $\{m_{21}, m_{22}, m_{23}\}$ being perfect squares in $\mathbb{Q}(\sqrt{3})$ is equivalent to finding points on an elliptic curve over $\mathbb{Q}(\sqrt{3})$. For example, $m_{21} = \Box, m_{23} = \Box$ demands

$$\begin{cases} 
4(1 - \sqrt{3})\alpha^2 + 4(1 - \sqrt{3})\alpha\beta + (1 + \sqrt{3})^2\beta^2 = \Box, \\
4(1 + \sqrt{3})\alpha^2 + 4(1 + \sqrt{3})\alpha\beta + (1 - \sqrt{3})^2\beta^2 = \Box
\end{cases}$$

which is the equation of an elliptic curve having cubic model

$$Y^2 = X(X^2 + 8X + 4).$$

This curve is of rank 1 over $\mathbb{Q}(\sqrt{3})$ and has generator of infinite order equal to $P = (1, \sqrt{3})$.

The multiples of $P$ lead to an infinite sequence of squares such as (2). Points $Q$ and $Q'$ that differ only by a torsion element lead to symmetries of the same magic square, and so magic squares that arise in this way come from the sequence $mP, m \in \mathbb{Z}$. For example, $P$ corresponds to $(\alpha, \beta) = (2, -1)$, giving a trivial square; $2P$ corresponds to $(\alpha, \beta) = (4, 9)$, leading to the square (2); and $3P$ corresponds to $(\alpha, \beta) = (2926, -3041)$, giving the square

$$\begin{vmatrix}
(3156 - 2926\sqrt{3})^2 & (2811 + 3041\sqrt{3})^2 & (5967 + 115\sqrt{3})^2 \\
(4749 + 2089\sqrt{3})^2 & 2^2 \cdot 3 \cdot 37 \cdot 43 \cdot 1867 & (4749 - 2089\sqrt{3})^2 \\
(5967 - 115\sqrt{3})^2 & (2811 - 3041\sqrt{3})^2 & (3156 + 2926\sqrt{3})^2
\end{vmatrix}.$$
The other possibility, that \( m_{21} = \square, m_{22} = \square \), demands
\[
\begin{align*}
&4(1 - \sqrt{3})\alpha^2 + 4(1 - \sqrt{3})\alpha \beta + (1 + \sqrt{3})^2 \beta^2 = \square, \\
&\alpha^2 + \alpha \beta + \beta^2 = \square.
\end{align*}
\]
This is the equation of an elliptic curve over \( \mathbb{Q}(\sqrt{3}) \), with cubic model
\[
Y^2 = X(X^2 + 2X - 2).
\]
This curve is of rank 2 over \( \mathbb{Q}(\sqrt{3}) \) and has generators of infinite order equal to \( P_1 = (1, 1), P_2 = (-1, \sqrt{3}) \). A two-dimensional family of magic squares arises from the pullbacks of combinations of the two generators. For example, \( P_1 \) gives rise to
\[
\begin{bmatrix}
(23 - 7\sqrt{3})^2 & (1 - 4\sqrt{3})^2 & (22 - 3\sqrt{3})^2 \\
(2 + 9\sqrt{3})^2 & (7 - 11\sqrt{3})^2 & 577 - 344\sqrt{3} \\
(11 - 8\sqrt{3})^2 & 5^2(2 - 3\sqrt{3})^2 & (1 + 7\sqrt{3})^2
\end{bmatrix},
\]
\( P_2 \) to
\[
\begin{bmatrix}
(5 + 3\sqrt{3})^2 & (5 - 4\sqrt{3})^2 & (10 - \sqrt{3})^2 \\
(10 - 3\sqrt{3})^2 & (1 - 5\sqrt{3})^2 & 5(5 + 8\sqrt{3}) \\
7^2 & (2 + 5\sqrt{3})^2 & 5^2(1 - \sqrt{3})^2
\end{bmatrix},
\]
\( P_1 + P_2 \) to
\[
\begin{bmatrix}
(95 - 17\sqrt{3})^2 & (205 - 68\sqrt{3})^2 & (110 - 51\sqrt{3})^2 \\
5^2(26 - 17\sqrt{3})^2 & (83 - 85\sqrt{3})^2 & 18553 - 6120\sqrt{3} \\
5^2(17 - 20\sqrt{3})^2 & (34 - 5\sqrt{3})^2 & 7^2(17 - 15\sqrt{3})^2
\end{bmatrix},
\]
and \( 2P_2 \) to
\[
\begin{bmatrix}
(187 - 243\sqrt{3})^2 & (166 + 203\sqrt{3})^2 & (353 - 40\sqrt{3})^2 \\
(227 + 100\sqrt{3})^2 & (37 - 233\sqrt{3})^2 & 317(779 - 252\sqrt{3}) \\
(446 - 7\sqrt{3})^2 & (283 - 180\sqrt{3})^2 & (163 + 173\sqrt{3})^2
\end{bmatrix}.
\]
None of the squares we computed had the ninth element \( m_{23} \) a perfect square in \( \mathbb{Q}(\sqrt{3}) \).

5. As a final remark, we observe that non-trivial \( 4 \times 4 \) magic squares of squares are not difficult to construct. One such example is the following:
\[
\begin{bmatrix}
37^2 & 23^2 & 21^2 & 22^2 \\
1^2 & 18^2 & 47^2 & 17^2 \\
38^2 & 11^2 & 13^2 & 33^2 \\
3^2 & 43^2 & 2^2 & 31^2
\end{bmatrix}.
