Polynomial continued fractions

by

D. Bowman and J. Mc Laughlin (Champaign-Urbana, IL)

1. Introduction. A polynomial continued fraction is a continued fraction $K_{n=1}^{\infty}a_n/b_n$ where $a_n$ and $b_n$ are polynomials in $n$. Most well known continued fractions are of this type. For example the first continued fractions giving values for $\pi$ (due to Lord Brouncker, first published in [10]) and $e$ ([3]) are of this type:

\begin{align*}
\frac{4}{\pi} &= 1 + \sum_{n=1}^{\infty} \frac{(2n - 1)^2}{2}, \\
e &= 2 + \frac{1}{1 + \sum_{n=1}^{\infty} \frac{n}{n + 1}}.
\end{align*}

Here we use the standard notations

\[ K_{n=1}^{N} a_n/b_n := \frac{a_1}{b_1 + \frac{a_2}{b_2 + \frac{a_3}{b_3 + \ldots + \frac{a_N}{b_N}}}} = \frac{a_1}{b_1 + \frac{a_2}{b_2 + \frac{a_3}{b_3 + \ldots + \frac{a_N}{b_N}}}}. \]

We write $A_N/B_N$ for the above finite continued fraction written as a rational function of the variables $a_1, \ldots, a_N, b_1, \ldots, b_N$. By $K_{n=1}^{\infty}a_n/b_n$ we mean the limit of the sequence $\{A_n/B_n\}$ as $n$ goes to infinity, if the limit exists.

The first systematic treatment of this type of continued fraction seems to be in Perron [7] where degrees through two for $a_n$ and degree one for $b_n$ are studied. Lorentzen and Waadeland [6] also study these cases in detail and they evaluate all such continued fractions in terms of hypergeometric series. There is presently no such systematic treatment for cases of higher degree and examples in the literature are accordingly scarcer. Of particular interest are cases where the degree of $a_n$ is less than or equal to the degree of $b_n$. These cases are interesting from a number theoretic standpoint since the values of the continued fraction can then be approximated exceptionally

2000 Mathematics Subject Classification: Primary 11A55.
well by rationals and irrationality measures may be given. When the degrees are equal, the value can be rational or irrational and certainly the latter when the first differing coefficient is larger in \( b_n \). (Here we count the first coefficient as the coefficient of the largest degree term.) Irrationality follows from the criterion given by Tietze, extending the famous Theorem of Legendre (see Perron [7, pp. 252–253]):

**Tietze’s Criterion.** Let \( \{a_n\}_{n=1}^{\infty} \) be a sequence of integers and \( \{b_n\}_{n=1}^{\infty} \) be a sequence of positive integers, with \( a_n \neq 0 \) for any \( n \). If there exists a positive integer \( N_0 \) such that

\[
\begin{align*}
   b_n &\geq |a_n|, \\
   b_n &\geq |a_n| + 1 \quad \text{for} \quad a_{n+1} < 0
\end{align*}
\]

for all \( n \geq N_0 \) then \( K_{n=1}^{\infty} a_n / b_n \) converges and its limit is irrational.

It would seem from the literature that finding cases of equal degrees or even close degrees is difficult. If one picks a typical continued fraction from published tables, the degree of the numerator tends to be twice that of the denominator. One easy way in which this can arise is when the continued fraction is equal to a series after using the Euler transformation:

\[
\sum_{n \geq 0} a_n = a_0 + \frac{a_1}{1 + \frac{-a_2}{a_1 + \frac{-a_3}{a_2 + \frac{-a_4}{a_3 + \frac{-a_5}{a_4 + \ldots}}}}}
\]

If one side of this equality converges, then so does the other as the \( n \)th approximants are equal. The Euler transformation is easily proved by induction.

In this formula, if the terms of the series are rational functions of the index of fixed degree, then in the continued fraction after simplification, one will get the degrees of the numerators to be at least twice those of the denominators. The continued fraction for \( \pi \) given by (1.1) is an example of this phenomenon. Another example of this is the series definition of Catalan’s constant:

\[
C = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)^2}
\]

which, by (1.4), transforms into the continued fraction given by

\[
C = \frac{1}{1 + \frac{1^4}{8 + \frac{3^4}{16 + \frac{5^4}{24 + \ldots}}}}
\]

Here the degree of the numerator is four times that of the denominator. This continued fraction appears to be new.

Taking contractions of continued fractions (see, for example, Jones and Thron [5, pp. 38–43]) also leads to a relative increase in the degree of the numerator over that of the denominator. For example, forming the even part of the continued fraction will cause a continued fraction with equal degrees
to be transformed into one where the ratio of the degrees of the numerator
and denominator polynomials is four to three.

The even part of the continued fraction $K_{n=1}^\infty a_n/b_n$ is equal to
\[
\frac{a_1 b_2}{a_2 + b_1 b_2 + a_3 b_4 + b_2(a_4 + b_3 b_4) + \frac{-a_4 a_5 b_2 b_6}{a_5 b_6 + b_4(a_6 + b_5 a_6) + a_7 b_8 + b_6(a_8 + b_7 a_8) + \ldots}}.
\]

Other work on polynomial continued fractions was done by Ramanujan [1, Chapter 12]. He gave several cases of equal degree in which the sum is rational. For example, Ramanujan gave the following: If $x$ is not a negative integer then
\[
\sum_{n=1}^\infty \frac{x + n}{x + n - 1} = 1.
\]

Despite the simplicity of this formula, Ramanujan did not give a proof; the first proof seems to have been given by Berndt [1, p. 112].

In this paper we examine a large number of infinite classes of polynomial continued fractions in which the degrees are equal, or close. Our results follow from a theorem of Pincherle and a variant of the Euler transformation discussed above. We obtain generalizations of Ramanujan’s results in which the degrees are equal and the values rational as well as cases of equal degree with irrational limits. Many of our theorems give infinite families of continued fractions. While we concentrate on polynomial continued fractions, many of the results hold in more general cases. Here are some special cases of our general results (proofs are given throughout the paper):

\[
\sum_{n=1}^\infty \frac{n^\alpha + 1}{n^\alpha} = 1 \quad \text{for } \alpha > 0.
\]

\[
1 - \frac{1}{1 + \sum_{n=1}^\infty \frac{n^2}{n^2 + 2n}} = J_0(2),
\]

where $J_0(x)$ is the Bessel function of the first kind of order 0.

\[
2 + \sum_{n=1}^\infty \frac{2n^2 + n}{2n^2 + 5n + 2} = \frac{1}{\sqrt{2} \csc(\sqrt{2}) - 1}.
\]

(Notice that the irrationality criterion mentioned above means that the last two quantities on the right are irrational.)

\[
\sum_{n=1}^\infty \frac{n^{12} + 2n^{11} + n^{10} + 4n + 5}{n^{12} + 4n - 4} = 4.
\]

\[
\sum_{n=2}^\infty \frac{6n^7 + 6n^6 + 2n^5 + 3n + 2}{6n^7 - 6n^6 + 2n^5 + 3n - 5} = 7.
\]
\[
K = \frac{3n^6 - 3n^4 + n^3 + 6n^2 + 6n - 1}{3n^6 - 9n^5 + 6n^4 + n^3 + 6n^2 - 12n - 2} = 1.
\]

2. Infinite polynomial continued fractions with rational limits. In this section we derive some general results about the convergence and values of polynomial continued fractions in infinite families. We begin with the following theorem of Pincherle [9]:

**Theorem 1 (Pincherle).** Let \( \{a_n\}_{n=1}^{\infty} \), \( \{b_n\}_{n=1}^{\infty} \) and \( \{G_n\}_{n=1}^{\infty} \) be sequences of real or complex numbers satisfying \( a_n \neq 0 \) for \( n \geq 1 \) and for all \( n \geq 1 \),

\[
G_n = a_n G_{n-2} + b_n G_{n-1}.
\]

Let \( \{B_n\}_{n=1}^{\infty} \) denote the denominator convergents of the continued fraction \( K_{n=1}^{\infty} a_n/b_n \). If \( \lim_{n \to \infty} G_n/B_n = 0 \) then \( K_{n=1}^{\infty} a_n/b_n \) converges and its limit is \( -G_0/G_{-1} \).

**Proof.** See, for example, Lorentzen and Waadeland [6, p. 202].

For many sequences it may be difficult to decide whether the condition \( \lim_{n \to \infty} G_n/B_n = 0 \) is satisfied. Below are some conditions governing the growth of the \( B_n \)'s which will be useful later.

(i) Let \( a_n \) and \( b_n \) be non-constant polynomials such that \( a_n \geq 1, b_n \geq 1 \) for \( n \geq 1 \), and suppose \( b_n \) is a polynomial of degree \( k \). If the leading coefficient of \( b_n \) is \( D \), then given \( \varepsilon > 0 \), there exists a positive constant \( C_1 = C_1(\varepsilon) \) such that \( B_n \geq C_1(|D|/(1 + \varepsilon))^{n}(n!)^k \).

(ii) If \( a_n \) and \( b_n \) are positive numbers \( \geq 1 \), then there exists a positive constant \( C_3 \) such that \( B_n \geq C_3 \phi^n \) for \( n \geq 1 \), where \( \phi \) is the golden ratio \((1 + \sqrt{5})/2\).

**Corollary 1.** If \( m \) is a positive integer and \( b_n \) is any polynomial of degree \( \geq 1 \) such that \( b_n \geq 1 \) for \( n \geq 1 \), then

\[
\sum_{n=1}^{\infty} \frac{mb_n + m^2}{b_n} = m.
\]

**Proof.** With \( a_n = mb_n + m^2 \) for \( n \geq 1 \), and \( G_n = (-1)^{n+1}m^{n+1} \) for \( n \geq -1 \), \( \{a_n\}_{n=1}^{\infty}, \{b_n\}_{n=1}^{\infty} \) and \( \{G_n\}_{n=-1}^{\infty} \) satisfy equation (2.1). By (i) above

\[
\lim_{n \to \infty} G_n/B_n = \lim_{n \to \infty} (-1)^{n+1}m^{n+1}/B_n = 0 \Rightarrow \sum_{n=1}^{\infty} \frac{a_n}{b_n} = -G_0/G_{-1} = m.
\]

A special case is where \( m = 1 \), in which case \( |G_n| = 1 \) for all \( n \), and all that is necessary is that \( \lim_{n \to \infty} B_n = \infty \). The following generalization of the result (1.5) of Ramanujan for positive numbers greater than 1 follows easily:
Polynomial continued fractions

If \( \{b_n\}_{n=1}^\infty \) is any sequence of positive numbers with \( b_n \geq 1 \) for \( n \geq 1 \) then

\[
\frac{b_n + 1}{\prod_{n=1}^{\infty} b_n} = 1.
\]

Letting \( b_n = n^\alpha, \alpha > 0 \), gives (1.6) in the introduction (1).

Entry 12 from the chapter on continued fractions in Ramanujan’s second notebook [1, p. 118] follows as a consequence of the above theorem:

**Corollary 2.** If \( x \) and \( a \) are complex numbers, where \( a \neq 0 \) and \( x \neq -ka \), where \( k \) is a positive integer, then

\[
\frac{x + a}{a + \prod_{n=1}^{\infty} \left((-1)^n x + na\right) - a^2} = 1.
\]

**Proof.** Note that

\[
\frac{x + a}{a + \prod_{n=1}^{\infty} \left((-1)^n x + na\right) - a^2} = \frac{x/a + 1}{1 + \prod_{n=1}^{\infty} \left((-1)^n x/a + (n+1)\right) - a^2}.
\]

Replace \( x/a \) by \( m \) to simplify notation; the result will follow if it can be shown that

\[
m = \prod_{n=1}^{\infty} \frac{(m+n)^2 - 1}{1} = \prod_{n=1}^{\infty} \frac{(m+n-1)(m+n+1)}{1}.
\]

With \( G_{-1} = 1, G_n = (-1)^n \prod_{i=0}^{n}(m+i) \) for \( n \geq 0 \), and \( b_n = 1, a_n = (m+n-1)(m+n+1) \) for \( n \geq 1 \), \( \{a_n\}_{n=-1}^{\infty}, \{b_n\}_{n=1}^{\infty} \) and \( \{G_n\}_{n=-1}^{\infty} \) satisfy equation (2.1) so that the result will follow from Theorem 1 if it can be shown that \( \lim_{n \to \infty} G_n/B_n = 0 \), in which case the continued fraction will converge to \( -G_0/G_{-1} = m \). However, an easy induction shows that for \( k \geq 1 \),

\[
B_{2k+1} = (k+1) \prod_{i=2}^{2k+1} (m+i) \quad \text{and} \quad B_{2k} = (m+k+1) \prod_{i=2}^{2k} (m+i).
\]

Thus \( \lim_{n \to \infty} G_n/B_n = 0 \), and the result follows. 

**Corollary 3.** Let \( m \) be a positive integer and let \( b_n \) be any polynomial of degree \( \geq 1 \) such that \( b_n \geq 1 \) for \( n \geq 1 \) and either degree \( b_n > 1 \) or if degree \( b_n = 1 \) then its leading coefficient is \( D > m \). Then

\[
\prod_{n=1}^{\infty} \frac{mn b_n + m^2 n(n+1)}{b_n} = m.
\]

(1) Lorentzen and Waadeland give an exercise [6, p. 234, question 15(d)] which effectively involves a similar result in the case where \( b_n \) belongs to a certain family of quadratic polynomials in \( n \) over the complex numbers.
Proof. Letting \( G_n = (-1)^{n+1}m^{n+1}(n+1)! \) for \( n \geq -1 \) and \( a_n = mnb_n + m^2n(n+1) \) for \( n \geq 1 \), one sees that \( \{a_n\}_{n=1}^{\infty}, \{b_n\}_{n=1}^{\infty}, \{G_n\}_{n=-1}^{\infty} \) satisfy equation (2.1). By (i), \( \lim_{n \to \infty} G_n/B_n = 0 \Rightarrow K_{n-1}^\infty a_n/b_n = -G_0/G_{-1} = m. \]

Theorem 1 does not say directly how to find the value of all polynomial continued fractions \( K_{n=1}^\infty a_n/b_n \) as it does not say how the sequence \( G_n \) can be found or even if such a sequence can be found. However, Algorithm Hyper (see [8]) can be used to determine if a hypergeometric solution \( G_n \) exists to equation (2.1) and, if such a solution exists, the algorithm will output \( G_n \), enabling the limit of the continued fraction to be found, if \( G_n \) satisfies \( \lim_{n \to \infty} G_n/B_n = 0 \).

Even if for the particular polynomial sequences \( a_n \) and \( b_n \) it turns out that the sequence \( G_n \) found does not satisfy \( \lim_{n \to \infty} G_n/B_n = 0 \), then these three sequences \( a_n, b_n \) and \( G_n \) may be used to find the value of infinitely many other continued fractions when \( G_n \) is a polynomial or rational function in \( n \).

The following proposition shows how, given any one solution of (2.1), one can find the value of infinitely many other polynomial continued fractions in an easy way.

**Proposition 1.** Suppose that there exist complex sequences \( \{G_n\}_{n=-1}^{\infty}, \{a_n\}_{n=1}^{\infty}, \{b_n\}_{n=1}^{\infty} \) satisfying
\[
 a_nG_{n-2} + b_nG_{n-1} - G_n = 0.
\]

Let \( f_n \) be any sequence, let \( s_n = f_nG_{n-1} + a_n \) be such that \( s_n \neq 0 \) for \( n \geq 1 \), and let \( t_n = f_nG_{n-2} - b_n \). Let \( A_n/B_n \) denote the convergents to \( K_{n=1}^\infty s_n/t_n \). If \( \lim_{n \to \infty} G_n/B_n = 0 \) then \( K_{n=1}^\infty s_n/t_n \) converges and its limit is \( G_0/G_{-1} \).

**Proof.** Let \( G_n' = (-1)^{n+1}G_n \). Then
\[
 s_nG_{n-2} + t_nG_{n-1} - G_n = (-1)^{n+1}(a_nG_{n-2} + b_nG_{n-1} - G_n) = 0.
\]

Thus \( \{G_n'\}_{n=-1}^{\infty}, \{s_n\}_{n=1}^{\infty}, \{t_n\}_{n=1}^{\infty} \) satisfy the conditions of Theorem 1 so \( K_{n=1}^\infty s_n/t_n \) converges and its limit is \( -G_0'/G_{-1}' = G_0/G_{-1}. \)

Entry 9 from the chapter on continued fractions in Ramanujan’s second notebook [1, pp. 114--115] follows in case \( a \) is real and positive and \( x \) is real as a consequence of the above proposition:

**Corollary 4.** Let \( a \) be a real positive number and let \( x \) be a real number such that \( x \neq -ka \) where \( k \) is a positive integer. Then
\[
 \frac{x+a+1}{x+1} = \lim_{n=1}^\infty \frac{x+na}{x+(n-1)a-1}.
\]

**Proof.** It is enough to prove this for \( x-1 > 0 \) since for \( n \) sufficiently large \( x+(n-1)a-1 > 0 \) and then the result will hold for a tail of the
continued fraction and the resulting finite continued fraction will collapse from the bottom up to give the result. Let \( G_n = (x + (n+1)a + 1)/(x+1) \). Put \( f_n = x + 1, a_n = -1 \) and \( b_n = 2 \) so that \( a_nG_{n-2} + b_nG_{n-1} - G_n = 0 \), \( x + na = f_nG_{n-1} + a_n \) and \( x + (n-1)a - 1 = f_nG_{n-2} - b_n \). Since \( G_n \) is a degree 1 polynomial in \( n \), and \( x + na, x + (n-1)a - 1 > 0 \) for \( n \geq 1 \), it can easily be shown that \( \lim_{n \to \infty} G_n/B_n = 0 \) and so by Proposition 1 the continued fraction converges to \( G_0/G_{-1} = (x + a + 1)/(x+1) \).

**Remarks.** (1) In Proposition 1 any polynomial \( G_n \) satisfying (2.2) can always be assumed to have positive leading coefficient (if necessary multiply (2.2) by \(-1\)). If \( f_n \) is then taken to be a polynomial of sufficiently high degree with leading positive coefficient then both \( s_n \) and \( t_n \) will be polynomials with positive leading coefficients so that there exists a positive integer \( N_0 \) so that for all \( n \geq N_0, s_n, t_n > 0 \). If it happens that for some \( m \geq N_0 \) both \( B_m \) and \( B_{m+1} \) are of the same sign then \( B_n \) will go to \(+\infty\) or \(-\infty\) exponentially fast. In these circumstances \( \lim_{n \to \infty} G_n/B_n = 0 \), since \( G_n \) is only of polynomial growth.

In many of the following corollaries \( f_n \) will be restricted so as to have \( N_0 \) small (typically in the range \( 1 \leq N_0 \leq 3 \)), but of course there are \( f_n \) for which this is not the case but for which the results claimed in the corollaries hold.

(2) One approach is to take the polynomial \( G_n \) as given and search for polynomials \( a_n \) and \( b_n \) satisfying equation (2.2). It can be assumed that \( \deg(a_n), \deg(b_n) < \deg(G_n) \). This follows since if a solution exists with \( \deg(a_n) \geq \deg(G_n) \) then the Euclidean algorithm can be used to write \( a_n = p_nG_{n-1} + a'_n, b_n = q_nG_{n-2} + b'_n \), where \( p_n, q_n, a'_n \) and \( b'_n \) are polynomials in \( n \). Substituting into (2.2) and comparing degrees gives that (2.2) holds with \( a_n \) replaced with \( a'_n \) and \( b_n \) replaced with \( b'_n \).

(3) Given any non-constant polynomial \( G_n \), one can equate coefficients in (2.2) to derive expressions for the coefficients of \( a_n \) and \( b_n \) in terms of those of \( G_n \). If \( G_n \) has degree \( k \) and \( a_n \) and \( b_n \) both have degree \( k-1 \), then (2.2) is a polynomial identity of degree \( 2k - 1 \), giving \( 2k \) equations for the \( 2k \) coefficients of \( a_n \) and \( b_n \) \((2)\).

In practice these equations and the requirement that the coefficients of \( s_n \) and \( t_n \) be integers introduces conditions on the coefficients of \( G_n \). For example, if there exist \( G_n = an^2 + bn + c, a_n = dn + e, \) and \( b_n = fn + g \), polynomials with integral coefficients, satisfying (2.2), then

\((2)\) Starting with \( a_n \) and \( b_n \), arbitrary polynomials of a certain degree, it is possible to look for solutions \( G_n \) satisfying (2.2) with coefficients defined in terms of those of \( a_n \) and \( b_n \) using the Hyper Algorithm (see [8]). However there is no certainty that the solutions (if they exist) will be polynomials or that they will have any particular desired degree.
\[ d = -f = \frac{4a^2}{a^2 - b^2 + 4ac}, \]
\[ e = \frac{-3a^2 + b^2 + 2ab - 4ac}{a^2 - b^2 + 4ac}, \]
\[ g = \frac{12a^2 - 2ab - 2b^2 + 8ac}{a^2 - b^2 + 4ac}, \]
giving restrictions on the allowable values of \(a, b\) and \(c\).

(Parts (ii)–(ix) of the following corollary correspond, respectively, to the solutions \(\{a = b = m, c = 1\}, \{a = 1, b = 4, c = 4\}, \{a = m^2, b = 3m^2 - 2m, c = 2m^2 - 2m + 1\}, \{a = m^2, b = m^2 + 2m, c = 2m + 1\}, \{a = m, b = 3m, c = 2m + 1\}, \{a = m, b = m - 2, c = -1\}, \{a = m, b = 3m + 2, c = 2m + 3\} and \{a = 4m, b = 16m^2 + 8m + 1, c = 16m^3 + 16m^2 + 5m + 1\}.)

Proposition 1 is too general to easily calculate the limit of particular polynomial continued fractions. The following corollary enables these limits to be calculated explicitly in a number of particular cases.

**Corollary 5.** Let \(m\) be a positive integer, \(k\) a positive integer greater than \(m\) and \(\{f_n\}_{n=1}^{\infty}\) a non-constant polynomial sequence such that \(f_n \geq 1\) for \(n \geq 1\). For each of continued fractions below assume that \(f_n\) is such that no numerator partial quotient is equal to zero. (This holds automatically in cases (i)–(vi).)

\[ \frac{\infty}{\sum_{n=1}^{\infty} (mn + k - m)f_n - 1}{\sum_{n=1}^{\infty} (mn + k - 2m)f_n - 2} = \frac{k}{k - m}. \]

\[ \frac{\infty}{\sum_{n=1}^{\infty} (n^2 - n)m + 1)}f_n + mn - 1}{\sum_{n=1}^{\infty} ((n^2 - 3n + 2)m + 1) + mn - (2m + 2)} = 1. \]

\[ \frac{\infty}{\sum_{n=1}^{\infty} (n + 1)^2f_n + 4n + 5}{\sum_{n=1}^{\infty} f_n + 4n - 4} = 4. \]

\[ \frac{\infty}{\sum_{n=1}^{\infty} f_n(m^2n^2 + n(m^2 - 2m) + 1) + mn + m - 2}{\sum_{n=1}^{\infty} f_n(m^2n^2 - n(m^2 + 2m) + 2m + 1) + mn - m - 3} = 2m^2 - 2m + 1. \]

\[ \frac{\infty}{\sum_{n=1}^{\infty} f_n(m^2n^2 + n(2m - m^2) + 1) + mn}{\sum_{n=1}^{\infty} f_n(m^2n^2 - n(3m^2 - 2m) + 2m^2 + 2m + 1) + mn - 2m - 1} = 2m + 1. \]

\[ \frac{\infty}{\sum_{n=1}^{\infty} f_n(n(n + 1)m + 1) + mn + m - 1}{\sum_{n=1}^{\infty} f_n(n(n - 1)m + 1) + mn - m - 2} = 2m + 1. \]

(vii) Let \(A_n/B_n\) denote the convergents to the continued fraction below and suppose \(\lim_{n \to \infty} n^2/B_n = 0\). Then

\[ \frac{\infty}{\sum_{n=1}^{\infty} f_n((n - 1)^2m + (m - 2)(n - 1) - m^2n + m - 1}{\sum_{n=1}^{\infty} f_n((n - 2)^2m + (m - 2)(n - 2) - 1 - m^2(n - 2) + m - 2} = -1. \]
(viii) \[
\frac{\sum_{k=1}^{\infty} f_n(n(n+1)m+2n+1) - (m^2(n+1)+m+1)}{\sum_{k=1}^{\infty} f_n(n(n-1)m+2n-1) - (m^2(n-1)+m+2)} = 2m + 3.
\]
\[
-1 - 8m - 32m^2 - 128m^3 - 64m^2n + (m + 16m^3 + (1 + 16m^2)n + 4mn^2)f_n
\]
\[
= 1 + 5m + 16m^2 + 16m^3
\]
\[
\frac{m + 16m^2}{m + 16m^3}.
\]

Proof. In each case below an easy check shows that with the given choices for \(\{G_n\}_{n=-1}^{\infty}, \{a_n\}_{n=1}^{\infty} \) and \(\{b_n\}_{n=1}^{\infty}\): equation (2.2) holds; the continued fraction in question corresponds to the continued fraction \(K_{n=1}^{\infty} s_n/t_n\) of Proposition 1; if \(\{A_n/B_n\}\) are the convergents to this continued fraction then \(\lim_{n\to\infty} G_n/B_n = 0\); and (by fact or assumption) no \(s_n\) is 0. Finally, the limit of the continued fraction is \(G_0/G_{-1}\). The fact that some early partial quotients may be negative does not affect any of the results—a tail of the continued fraction will have all terms positive so that \(\lim_{n\to\infty} G_n/B_n = 0\) will hold for the tail which will then converge and the continued fraction will then collapse from the bottom up to give the result.

Remark. In some cases the result holds if \(f_n\) is a constant polynomial such that \(f_n \geq 1\) for \(n \geq 1\).

- (i) Let \(G_n = mn + k, a_n = -1\) and \(b_n = 2\).
- (ii) Let \(G_n = n(n+1)m + 1, a_n = mn - 1\) and \(b_n = -mn + (2m + 2)\).
- (iii) Let \(G_n = (n+2)^2, a_n = 4n + 5\) and \(b_n = -4n + 4\).
- (iv) Let \(G_n = m^2n^2 + n(3m^2 - 2m) + 2m^2 - 2m + 1, a_n = mn + m - 2\) and \(b_n = -mn + m + 3\).
- (v) Let \(G_n = n(n+1)m + 2m + 1, a_n = mn\) and \(b_n = -mn + 2m + 1\).
- (vi) Let \(G_n = (n+2)(n+1)m + 1, a_n = mn + m - 1\) and \(b_n = -mn + m + 2\).
- (vii) Let \(G_n = mn^2 + (m-2)n - 1, a_n = -m^2n + m - 1\) and \(b_n = m^2n - 2m^2 - m + 2\).
- (viii) Let \(G_n = (n+2)(n+1)m + 2n + 3, a_n = -(m^2n + m^2 + m + 1)\) and \(b_n = m^2(n-1) + m + 2\).
- (ix) Let \(G_n = 1 + 5m + 16m^2 + 16m^3 + (1 + 8m + 16m^2)n + 4mn^2, a_n = -1 - 8m - 32m^2 - 128m^3 - 64m^2n\) and \(b_n = 2 + 8m - 96m^2 + 128m^3 + 64m^2n\).

Examples. 1. Letting \(m = 5\) and \(f_n = 10n^8\) in (ii) above gives

\[
\sum_{n=1}^{\infty} \frac{(n^2 - n)5 + 1)10n^8 + 5n - 1)}{(n^2 - 3n + 2)5 + 1)10n^8 + 5n - 12} = 1.
\]
2. Also in (ii), letting \( f_n = n^8 \) and \( m \) be an arbitrary positive integer gives

\[
\prod_{n=1}^{\infty} \frac{(n^2 - n)m + 1)n^8 + nm - 1}{(n^2 - 3n + 2)m + 1)n^8 + mn - (2m + 2)} = 1.
\]

3. Letting \( f_n = 2n^5 \) and \( m = 3 \) in (vi) above gives (1.10) of the introduction. Similarly, letting \( f_n = n^{10} \) gives (1.9) of the introduction.

4. In (vii) above a general class of examples may be obtained by choosing \( m > 1 \) and \( f_n > nm^2 \) for \( n \geq 1 \). With the notation of the proposition it can easily be seen that \( s_n, t_n \geq 1 \) for \( n \geq 3 \). If \( f_n \) is such that \( B_2 \) and \( B_3 \) are negative, then \( B_n \) will be negative for all \( n \geq 2 \) and by a similar argument to the reasoning behind condition (ii), it will follow that \( \lim_{n \to \infty} n^2/B_n = 0 \) and the conditions of the corollary will be satisfied. For example, letting \( f_n = 16n \) and \( m = 3 \) gives

\[
\prod_{n=1}^{\infty} \frac{48n^3 - 80n^2 + 7n + 2}{48n^3 - 176n^2 + 135n + 19} = -1.
\]

All the examples in the last corollary were derived from solutions to equation (2.2) where \( G_n \) had degree 2. Table 1 below gives several families of solutions to equation (2.2), where \( G_n \) is of degree 3 in \( n \).

<table>
<thead>
<tr>
<th>( G_n )</th>
<th>( a_n )</th>
<th>( b_n )</th>
</tr>
</thead>
<tbody>
<tr>
<td>((n^2 - 1)mn + 1)</td>
<td>(2mn(n - 1) - 1)</td>
<td>(-2m(n^2 - 4n + 3) + 2)</td>
</tr>
<tr>
<td>((2n^2 + 3n + 1)mn + 1)</td>
<td>(-2n^2m(m - 2) + m^2n + m - 1)</td>
<td>(-n^2(4m - 2m^2) - n(7m^2 - 12m) + 6m^2 - 7m + 2)</td>
</tr>
<tr>
<td>((n^2 + 3n + 2)mn + 1)</td>
<td>(2n(n + 1)m - 1)</td>
<td>(-2n(n - 2)m + 2)</td>
</tr>
<tr>
<td>((n^3 + 6n^2 + 11n + 6)m + 1)</td>
<td>(2mn^2 + 6mn + 4m - 1)</td>
<td>(-2mn^2 + 2m + 2)</td>
</tr>
<tr>
<td>(mn^3 + 3mn^2 + n(2m - 3) - 2)</td>
<td>(-m^2n^2 - n(m^2 + m) + m - 1)</td>
<td>(m^2n^2 - n(2m^2 - m) - 4m + 2)</td>
</tr>
</tbody>
</table>

Considering the third and fourth row of entries in the Table 1, for example, there is the following corollary to Proposition 1:

**Corollary 6.** Let \( f_n \) be a polynomial in \( n \) such that \( f_n \geq 1 \) for \( n \geq 1 \) and let \( m \) be a positive integer.

(i) If \( f(2) > 2 \) then

\[
\prod_{n=1}^{\infty} \frac{f_n((n^2 - 1)mn + 1) + 2mn(n + 1) - 1}{f_n((n^2 - 3n + 2)mn + 1) + 2mn(n - 2) - 2} = 1.
\]
(ii) We have
\[
\lim_{K \to \infty} \frac{f_n((n^2 + 3n + 2)nm + 1) + 2mn^2 + 6mn + 4m - 1}{f_n((n^2 - 1)nm + 1) + 2(n^2 - 1)m - 2} = 6m + 1.
\]

Proof. (i) In the light of the fact that \(G_n, a_n\) and \(b_n\) satisfy (2.2) simply note that the numerator of the continued fraction is \(f_nG_{n-1} + a_n\) and that the denominator is \(f_nG_{n-2} - b_n\). It is easily seen that \(a_n \geq 1\) for all \(n \geq 1\) and that \(b_n \geq 1\) for all \(n \geq 2\). It can also be shown that \(B_2\) and \(B_3\) are positive for all \(m\) and \(f_n\) satisfying the conditions of the corollary. In the light of what was said in an earlier remark this is sufficient to ensure the result.

(ii) The proof of this follows the same lines as that of (i) above.

Taking \(f_n\) to be \(n^3\) and \(m = 3\) in part (i) gives (1.11) of the introduction.

One could continue to prove similar results by finding other solutions to equation (2.2) for degrees 2 or 3 or by going to higher degrees, but these corollaries should be sufficient to illustrate the principle at work.

3. Infinite polynomial continued fractions with irrational limits. In this section we use a continued fraction-to-series transformation equivalent to Euler’s transformation to sum some polynomial continued fractions with irrational limits.

THEOREM 2. For \(N \geq 1\),
\[
b_0 + \sum_{n=1}^{N} \frac{b_{n-1}x}{b_n - x} = \frac{1}{\sum_{n=0}^{N} (-1)^n x^n \prod_{i=0}^{n} b_i}.
\]

Thus, when \(N \to \infty\), the continued fraction converges if and only if the series converges.

Proof. See, for example, Chrystal [2, p. 516, equation (14)].

Remark. The irrationality criterion mentioned in the introduction means that if \(\{b_n\}_{n=0}^{\infty}\) is a sequence of integers, then the number \(\sum_{n=0}^{\infty} (-1)^n x^n / (b_0 b_1 \ldots b_n)\) is not rational for \(x = 1/m\), \(m\) being a non-zero integer, provided \(|mb_n - 1| \geq |mb_{n-1}| + 1\) for all \(n\) sufficiently large.

Corollary 7. For all non-zero integers \(m\) (and indeed for all non-zero real numbers \(m\)),
\[
6m^2 - 1 + \sum_{n=1}^{\infty} \frac{m^2(4n^2 + 2n)}{m^2(4n^2 + 10n + 6) - 1} = \frac{1}{(1/m) \csc(1/m) - 1}.
\]
Remarks. (1) Glaisher [4] states continued fraction expansions essentially equivalent to this one and the one in the next corollary.

(2) The irrationality criterion shows that \( \sin(1/m) \) is irrational for \( m \) either a non-zero integer or the square root of a positive integer.

Proof of Corollary 7. In Theorem 2 let \( b_n = (2n + 2)(2n + 3)m^2 \) and \( x = 1 \).

Corollary 8. For all non-zero integers \( m \) (and indeed for all non-zero real numbers \( m \)),

\[
2m^2 + \sum_{n=1}^{\infty} \frac{m^2(4n^2 - 2n)}{m^2(4n^2 + 6n + 2) - 1} = \frac{1}{1 - \cos(1/m)}.
\]

Note that the irrationality criterion shows that \( \cos(1/m) \) is irrational for \( m \) either a non-zero integer or the square root of a positive integer.

Proof of Corollary 8. In Theorem 2 let \( b_n = (2n + 1)(2n + 2)m^2 \) and \( x = 1 \).

Corollary 9. For all positive integers \( \nu \) and all non-zero integers \( m \) (and indeed for all non-zero real numbers \( m \)),

\[
(\nu + 1)4m^2 + \sum_{n=1}^{\infty} \frac{4m^2n(n + \nu)}{4m^2(n + 1)(n + \nu + 1)} - 1 = \frac{1}{1 - (\nu)!/(2m)^{\nu}J_\nu(1/m)},
\]

where \( J_\nu(x) \) is the Bessel function of the first kind of order \( \nu \).

The Tietze irrationality criterion shows that if \( \nu \) is a non-negative integer and \( m \) is a non-zero integer or the square root of a positive integer then \( J_\nu(\pm 1/m) \) is irrational.

Proof of Corollary 9. In Theorem 2, letting \( b_n = 4(n + 1)(\nu + n + 1)m^2 \) and \( x = 1 \) gives

\[
4(\nu + 1)m^2 + \sum_{n=1}^{\infty} \frac{n(\nu + n)4m^2}{(n + 1)(n + \nu + 1)4m^2 - 1} = \frac{1}{1 - (\nu)!/(2m)^{\nu}J_\nu(1/m)},
\]

from the power series expansion for \( J_\nu(x) \).

Taking \( \nu \) to be 0 and \( m = 2 \) gives (1.7) of the introduction. (1.8) of the introduction follows by letting \( m = 1/\sqrt{2} \) in Corollary 7.
Corollary 10. For all non-zero integers \(m\) (and indeed for all non-zero real numbers \(m\)),

\[
1 + \frac{1}{6m^3 - 1 + \sum_{n=2}^{\infty} \frac{(3n - 5)(3n - 4)(3n - 3)m^3}{(3n - 2)(3n - 1)(3n)m^3 - 1}} = \left(\frac{1}{3} \exp(-1/m) + \frac{2}{3} \exp(1/(2m)) \cos(\sqrt{3}/(2m))\right)^{-1}.
\]

Proof. In Theorem 2 let \(b_0 = 1, b_n = (3n - 2)(3n - 1)(3n)\) for \(n \geq 1\) and \(x = 1/m^3\). Then

\[
1 + \frac{1/m^3}{6 - 1/m^3 + \sum_{n=2}^{\infty} \frac{(3n - 5)(3n - 4)(3n - 3)(1/m^3)}{(3n - 2)(3n - 1)(3n) - 1/m^3}} = \sum_{n=0}^{\infty} \frac{(-1)^n(1/m^{3n})}{(3n)!}.
\]

Simplifying the continued fraction gives the left side and finally the right side equals \(\left(\frac{1}{3} \exp(-1/m) + \frac{2}{3} \exp(1/(2m)) \cos(\sqrt{3}/(2m))\right)^{-1}\).

By the Tietze criterion the irrationality of this last function follows when \(m\) is a non-zero integer or the real cube root of a non-zero integer.

Clearly many results similar to Corollaries 7–10 can be written down by choosing other polynomials for \(b_n\). These examples serve to illustrate the general idea.
