Abstract. We provide new sufficient convergence conditions for the local and semilocal convergence of Stirling’s method to a locally unique solution of a nonlinear operator equation in a Banach space setting. In contrast to earlier results we do not make use of the basic restrictive assumption in [8] that the norm of the Fréchet derivative of the operator involved is strictly bounded above by 1. The study concludes with a numerical example where our results compare favorably with earlier ones.

1. Introduction. In this study, we are concerned with the problem of approximating a locally unique fixed point $x^*$ of the equation

$$F(x) = x,$$

where $F$ is a Fréchet differentiable operator defined on an open convex subset of a Banach space $X$ with values in $X$.

Stirling’s method [10]

$$x_{n+1} = x_n - A_n^{-1}(x_n - F(x_n)), \quad A_n = I - F'(F(x_n)) \quad (n \geq 0)$$

has been used to generate a sequence converging to $x^*$ [1]–[4], [8]. In particular elegant local and semilocal convergence results have been given in [8] under the restrictive assumption that $\|F'(x)\|$ is strictly bounded above by 1. Moreover in the same study a favorable comparison between Stirling’s and Newton’s methods was given including examples where Stirling’s method converges but Newton’s fails to do so. Note that both methods require almost the same computational cost: the evaluation of $F$, $F'$ and the solution...
of a linear equation at each step. Here we provide a new local and semilocal convergence analysis for method (2) without making use of $\|F'(x)\| < 1$.

Finally we provide a numerical example where our results compare favorably with earlier ones [7], [8], [10].

2. Semilocal analysis of Stirling’s method. We provide the following result on majorizing sequences for Stirling’s method (2).

**Theorem 1.** Assume that there exist parameters $L_0 \geq 0$, $L \geq 0$ with $L_0 \leq L$, $\eta \geq 0$, and $\delta \in [0,1]$ such that

\[(\delta L_0 + L)\eta \leq \delta.\]  

Then the iteration $\{t_n\}$ $(n \geq 0)$ given by

\[t_0 = 0, \quad t_1 = \eta,\]

\[t_{n+2} = t_{n+1} + \frac{L(t_{n+1} - t_n)^2}{2(1 - L_0 t_{n+1})} \quad (n \geq 0)\]

is non-decreasing, bounded above by $t^{**} = 2\eta/(2 - \delta)$, and converges to some $t^*$ such that

\[0 \leq t^* \leq t^{**}.\]

Moreover, the following error bounds hold for all $n \geq 0$:

\[0 \leq t_{n+2} - t_{n+1} \leq \frac{\delta}{2} (t_{n+1} - t_n) \leq \left(\frac{\delta}{2}\right)^{n+1} \eta.\]

**Proof.** The result clearly holds if $\delta = 0$ or $L = 0$ or $\eta = 0$. Assume $\delta \neq 0$, $L \neq 0$ and $\eta \neq 0$. We must show that for all $k \geq 0$,

\[L(t_{k+1} - t_k) + \delta L_0 t_{k+1} \leq \delta,\]

\[t_{k+1} - t_k \geq 0, \quad -L_0 t_{k+1} > 0.\]

Estimate (6) then follows immediately from (4) and (7). We use induction on $k$. For $k = 0$ we have

\[L(t_1 - t_0) + \delta L_0 t_1 = L\eta + \delta L_0 \eta \leq \delta,\]

\[t_1 \geq t_0, \quad 1 - L_0 \eta > 0 \quad \text{(by (3))}.\]

But then (4) gives

\[0 \leq t_2 - t_1 \leq \frac{\delta}{2} (t_1 - t_0).\]
Assume (6) and (7) holds for all $k \leq n + 1$. Then

$$\begin{align*}
(8) \quad L(t_{k+2} - t_{k+1}) + \delta L_0 t_{k+2} & \leq L \eta \left( \frac{\delta}{2} \right)^{k+1} + \delta L_0 \left[ t_1 + \frac{\delta}{2} (t_1 - t_0) + \left( \frac{\delta}{2} \right)^2 (t_1 - t_0) \\ & \quad + \ldots + \left( \frac{\delta}{2} \right)^{k+1} (t_1 - t_0) \right] \\
& \leq L \eta \left( \frac{\delta}{2} \right)^{k+1} + \delta L_0 \eta \frac{1 - (\delta/2)^{k+2}}{1 - \delta/2} \\
& \leq L \eta \left( \frac{\delta}{2} \right)^{k+1} + \frac{2\delta L_0 \eta}{2 - \delta} \left[ 1 - (\frac{\delta}{2})^{k+2} \right] \\
& = \left\{ L \left( \frac{\delta}{2} \right)^{k+1} + \frac{2L_0 \delta}{2 - \delta} \left[ 1 - (\frac{\delta}{2})^{k+2} \right] \right\} \eta.
\end{align*}$$

By (3) and (8) it suffices to show

$$L \left( \frac{\delta}{2} \right)^{k+1} + \frac{2L_0 \delta}{2 - \delta} \left[ 1 - (\frac{\delta}{2})^{k+2} \right] \leq L + \delta L_0$$

or

$$\delta L_0 \left\{ \frac{2}{2 - \delta} \left( 1 - \left( \frac{\delta}{2} \right)^{k+2} \right) - 1 \right\} \leq L \left[ 1 - \left( \frac{\delta}{2} \right)^{k+1} \right]$$

or

$$\frac{2\delta}{2 - \delta} \left[ 1 - \left( \frac{\delta}{2} \right)^{k+2} \right] - \delta \leq 1 - \left( \frac{\delta}{2} \right)^{k+1}$$

or

$$\frac{(\delta - 1)(\delta + 2)}{2 - \delta} \leq \frac{(\delta - 1)(\delta + 2)}{2 - \delta} \left( \frac{\delta}{2} \right)^{k+1},$$

which is true by the choice of $\delta$. Hence, the first estimate in (7) holds for all $n \geq 0$. We must also show that

$$t_k \leq t^{**}. \tag{9}$$

For $k = 0, 1, 2$ we have

$$t_0 = 0 \leq t^{**}, \quad t_1 = \eta \leq t^{**}, \quad t_2 \leq \eta + \frac{\delta}{2} \eta = \frac{2 + \delta}{2} \eta \leq t^{**}.$$
Assume (9) holds for all \( k \leq n + 1 \). It follows from (6) that
\[
(10) \quad t_{k+2} \leq t_{k+1} + \frac{\delta}{2} (t_{k+1} - t_k) \leq t_k + \frac{\delta}{2} (t_k - t_{k-1}) + \frac{\delta}{2} (t_{k+1} - t_k)
\]
\[
\leq \ldots \leq t_1 + \frac{\delta}{2} (t_1 - t_0) + \ldots + \frac{\delta}{2} (t_k - t_{k-1}) + \frac{\delta}{2} (t_{k+1} - t_k)
\]
\[
\leq \eta + \frac{\delta}{2} \eta + \left( \frac{\delta}{2} \right)^2 \eta + \ldots + \left( \frac{\delta}{2} \right)^{k+1} \eta
\]
\[
= \left[ 1 + \frac{\delta}{2} + \left( \frac{\delta}{2} \right)^2 + \ldots + \left( \frac{\delta}{2} \right)^{k+1} \right] \eta
\]
\[
= \frac{1 - (\delta/2)^{k+2}}{1 - \delta/2} \eta < \frac{2}{2 - \delta} \eta = t^{**}.
\]
Moreover, we have
\[
L_0 t_{k+2} < \frac{2L_0 \eta}{2 - \delta} < 1 \quad \text{(by (3)).}
\]
Hence, the sequence \( \{t_n\} \) \( (n \geq 0) \) is bounded above by \( t^{**} \). It also follows from (4) that \( \{t_n\} \) \( (n \geq 0) \) is non-decreasing, and hence it converges to some \( t^* \) satisfying (5).

That completes the proof of Theorem 1. □

Below we show the main semilocal convergence theorem for Stirling’s method (2).

**Theorem 2.** Let \( F : D \subseteq X \to X \) be a Fréchet differentiable operator. Assume there exist a point \( x_0 \in D \) and parameters \( \eta \geq 0, \ell \geq 0, \ell_0 \geq 0, b \geq 0, a_0 \in [0, 1), \delta \in [0, 1] \) such that:

1. \( A_0^{-1} \in L(X, X) \),
2. \( \|A_0^{-1}(x_0 - F(x_0))\| \leq \eta \),
3. \( \|F(x) - F(x_0)\| \leq a_0\|x - x_0\| \quad (a_0 < 1) \),
4. \( \|F'(F(x))\| \leq b \),
5. \( \|A_0^{-1}[F'(F(x_0)) - F'(F(x))]\| \leq \ell_0\|F(x_0) - F(x)\| \),
6. \( \|A_0^{-1}[F'(x) - F'(y)]\| \leq \ell\|x - y\| \quad \text{for all } x, y, F(x_0), F(x) \in D \),
7. \( (L + \delta L_0)\eta \leq \delta \quad \text{for } L = (3 + 2b)\ell, L_0 = a_0\ell_0 \),
8. \( \bar{U}(x_0, t^*) = \{x \in X \mid \|x - x_0\| \leq t^* \} \subseteq D \),
9. \( t^* \geq \frac{\|x_0 - F(x_0)\|}{1 - a_0} \),

where \( t^* \) is given in Theorem 1. Then \( \{x_n\} \) \( (n \geq 0) \) generated by Stirling’s method (2) is well defined, remains in \( \bar{U}(x_0, t^*) \) for all \( n \geq 0 \), and converges
to a fixed point \(x^* \in \mathcal{U}(x_0, t^*)\) of the operator \(F\). Moreover, the following error bounds hold for all \(n \geq 0\):
\[
\|x_{n+2} - x_{n+1}\| \leq \frac{L}{2(1 - L_0\|x_{n+1} - x_0\|)}\|x_{n+1} - x_n\|^2 \leq t_{n+2} - t_{n+1},
\]
\[
\|x_n - x^*\| \leq t^* - t_n,
\]
where the sequence \(\{t_n\} (n \geq 0)\) is generated by (4). If there exists \(R > t^*\) such that
\[
\mathcal{U}(x_0, R) \subseteq D,
\]
\[
\ell_1(1 + b)\eta + aR + 2\ell_0a_0t^* \leq 2,
\]
then the fixed point \(x^*\) of the operator \(F\) is unique in \(U(x_0, R)\). Furthermore if \(R = t^*\) and strict inequality holds in (23), then \(x^*\) is unique in \(\mathcal{U}(x_0, t^*)\).

**Proof.** Let us prove that
\[
\|x_{k+1} - x_k\| \leq t_{k+1} - t_k,
\]
\[
\mathcal{U}(x_{k+1}, t^* - t_{k+1}) \subseteq \mathcal{U}(x_k, t^* - t_k),
\]
for all \(k \geq 0\). For every \(z \in \mathcal{U}(x_1, t^* - t_1)\),
\[
\|z - x_0\| \leq \|z - x_1\| + \|x_1 - x_0\| \leq t^* - t_1 + t_1 = t^* - t_0
\]
implies \(z \in \mathcal{U}(x_0, t^* - t_0)\). Since also
\[
\|x_1 - x_0\| = \|A_0^{-1}(x_0 - F(x_0))\| \leq \eta = t_1 - t_0,
\]
(25) and (26) hold for \(k = 0\). Suppose they hold for \(n = 0, 1, \ldots, k\). Then
\[
\|x_{k+1} - x_0\| \leq \sum_{i=1}^{k+1} \|x_i - x_{i-1}\| \leq \sum_{i=1}^{k+1} (t_i - t_{i-1}) = t_{k+1} - t_0 = t_{k+1}
\]
and
\[
\|x_k + \theta(x_{k+1} - x_k) - x_0\| \leq t_k + \theta(t_{k+1} - t_k) < t^*, \quad \theta \in [0, 1].
\]
Note also that for \(x \in \mathcal{U}(x_0, t^*)\),
\[
\|x_0 - F(x)\| \leq \|x_0 - F(x_0)\| + \|F(x_0) - F(x)\|
\]
\[
\leq \|x_0 - F(x_0)\| + a_0\|x_0 - x\|
\]
\[
\leq \|x_0 - F(x_0)\| + a_0t^* \leq t^* \quad (\text{by (19)}).
\]
That is, \(F(x) \in \mathcal{U}(x_0, t^*)\).

Using (13) and (15) for \(x \in \mathcal{U}(x_0, t^*)\), we get
\[
\|A_0^{-1}[A_0 - (I - F'(F(x)))]| \leq \|A_0^{-1}(F'(F(x)) - F'(F(x)))|\| \\
\leq \ell_0\|F(x_0) - F(x)\| \leq \ell_0a_0\|x_0 - x\| \\
\leq \ell_0a_0t^* < 1,
\]
by the choice of $t^*$. It follows from (27) and the Banach Lemma on invertible operators [7] that $A(x) = I - F'(F(x))$ is invertible with

$$
\|A(x)^{-1}A_0\| \leq [1 - \ell_0a_0\|x_0 - x\|]^{-1}.
$$

By (2) we get

$$
x_{k+1} - F(x_{k+1}) = x_k - A_k^{-1}(x_k - F(x_k)) - F(x_{k+1})
$$

$$
= A_k^{-1}[A_k(x_k - F(x_{k+1})) - (x_k - F(x_k))]
$$

$$
= A_k^{-1}[F(x_k) - F(x_{k+1}) - F'(F(x_k))(x_k - x_{k+1})]
$$

$$
- F'(F(x_k))(x_{k+1} - F(x_{k+1}))],
$$

so

$$
x_{k+1} - F(x_{k+1}) + A_k^{-1}F'(F(x_k))(x_{k+1} - F(x_{k+1}))
$$

$$
= A_k^{-1}[F(x_k) - F(x_{k+1}) - F'(F(x_k))(x_k - x_{k+1})],
$$

hence

$$
\{I + A_k^{-1}F'(F(x_k))\}(x_{k+1} - F(x_{k+1}))
$$

$$
= A_k^{-1}[F(x_k) - F(x_{k+1}) - F'(F(x_k))(x_k - x_{k+1})],
$$

and therefore

$$
x_{k+1} - F(x_{k+1}) = F(x_k) - F(x_{k+1}) - F'(F(x_k))(x_k - x_{k+1})
$$

$$
= \frac{1}{0} \int_{\theta}^1 [F'(\theta x_k + (1 - \theta)x_{k+1}) - F'(\theta F(x_k) + (1 - \theta)F(x_k))](x_k - x_{k+1}) d\theta.
$$

By composing both sides of (29) with $A_0^{-1}$ and using (14), (16), we get

$$
\|A_0^{-1}(x_{k+1} - F(x_{k+1}))\|
$$

$$
\leq \frac{\ell}{2} [\|x_k - F(x_k)\| + \|x_{k+1} - F(x_k)\|] \|x_{k+1} - x_k\|,
$$

(31) \quad \|x_k - F(x_k)\| \leq \|I + F'(F(x_k))\| \cdot \|x_{k+1} - x_k\|

$$
\leq (1 + b)\|x_{k+1} - x_k\|,
$$

(32) \quad \|x_{k+1} - F(x_k)\| \leq \|x_{k+1} - x_k\| + \|x_k - F(x_k)\|

$$
\leq \|x_{k+1} - x_k\| + (1 + b)\|x_{k+1} - x_k\|
$$

$$
= (2 + b)\|x_{k+1} - x_k\|.
$$

Moreover by (2), (28)–(32), we get

$$
\|x_{k+2} - x_{k+1}\| \leq \|A_{k+1}^{-1}A_0\| \cdot \|A_0^{-1}(x_{k+1} - F(x_{k+1}))\|
$$

$$
\leq \frac{\ell}{2} \frac{3 + 2b}{1 - \ell_0a_0\|x_{k+1} - x_0\|} \|x_{k+1} - x_k\|^2
$$

$$
\leq \frac{L}{2(1 - L_0t_{k+1})} (t_{k+1} - t_k)^2 = t_{k+2} - t_{k+1}.
$$
Thus for every $z \in \mathcal{U}(x_{k+2}, t^* - t_{k+1})$ we have
\[
\|z - x_{k+1}\| \leq \|z - x_{k+2}\| + \|x_{k+2} - x_{k+1}\| \\
\leq t^* - t_{k+2} + t_{k+2} - t_{k+1} = t^* - t_{k+1}.
\]

That is,
\[
(34) \quad z \in \mathcal{U}(x_{k+1}, t^* - t_{k+1}).
\]

Estimates (33) and (34) imply that (25) and (26) hold for $n = k + 1$.

Theorem 1 implies that $\{t_n\} \ (n \geq 0)$ is a Cauchy sequence. From (25) and (26) $\{x_n\} \ (n \geq 0)$ is also a Cauchy sequence, and so it converges to some $x^* \in \mathcal{U}(x_0, t^*)$ (since $\mathcal{U}(x_0, t^*)$ is a closed set) such that
\[
(35) \quad \|x^* - x_k\| \leq t^* - t_k.
\]

The combination of (33) and (34) yields $F(x^*) = x^*$.

To show uniqueness let $y^*$ be a fixed point of $F$ in $U(x_0, R)$. By (2) we obtain the approximation
\[
(36) \quad x_{k+1} - y^* = x_k - y^* - A_k^{-1}(x_k - F(x_k)) \\
= A_k^{-1}\{F(x_k) - F(y^*) - F'(F(x_k))(x_k - y^*)\} \\
= \left[ A_k^{-1} A_0 \right] A_0^{-1} \left\{ \frac{1}{0} [F'(\theta x_k + (1 - \theta)y^*)] \\
- F'(\theta F(x_k) + (1 - \theta)F(x_k))(x_k - y^*)d\theta \right\}.
\]

Hence, by (36) and (13)–(16), (24) we obtain
\[
(37) \quad \|x_{k+1} - y^*\| \leq \frac{\ell}{2} \frac{\|x_k - F(x_k)\| + \|F(x_k) - F(y^*)\|}{1 - \ell_0 a_0 \|x_k - x_0\|} \|x_k - y^*\| \\
\leq \frac{\ell}{2} \frac{(1 + b)\|x_{k+1} - x_k\| + a\|x_k - y^*\|}{1 - \ell_0 a_0 \|x_k - x_0\|} \|x_k - y^*\| \\
< \frac{\ell}{2} \frac{(1 + b)\eta + aR}{1 - \ell_0 a_0 t^*} \|x_k - y^*\| < \|x_k - y^*\|,
\]

which shows $\lim_{k \to \infty} x_k = y^*$. But we already showed $\lim_{k \to \infty} x_k = x^*$. That is,
\[
x^* = y^*.
\]

Finally the uniqueness in $\mathcal{U}(x_0, t^*)$ follows from (37) and (23) (holding as strict inequality).

That completes the proof of Theorem 2. ■

Remark 1. Condition (23) can be dropped. We can replace it by
\[
(38) \quad \ell(1 + b)\eta + a_0(t^* + R) + 2\ell_0 a_0 t^* \leq 2.
\]
Indeed, we have
\begin{align}
\|x_{k+1} - y^*\| &\leq \frac{\ell}{2} \frac{(1 + b)\|x_{k+1} - x_k\| + \|F(x_k) - F(x_0) + F(x_0) - F(y^*)\|}{1 - \ell_0 a_0 \|x_k - x_0\|} \|x_k - y^*\| \\
&\leq \frac{\ell}{2} \frac{\|x_{k+1} - x_k\| + a_0(\|x_0 - x_k\| + \|x_0 - y^*\|)}{1 - \ell_0 a_0 \|x_k - x_0\|} \|x_k - y^*\| \\
&< \frac{\ell}{2} \frac{(1 + b)\eta + a_0(t^* + \eta)}{1 - \ell_0 a_0 t^*} \|x_k - y^*\|,
\end{align}
which also shows \(\lim_{k \to \infty} x_k = y^*\). Hence, again we get \(x^* = y^*\).

3. Local analysis of Stirling’s method. Below we show the main local convergence theorem for Stirling’s method (2).

**Theorem 2.** Let \(F : D \subseteq X \to X\) be a Fréchet differentiable operator. Assume that there exist a fixed point \(x^*\) of the operator \(F\) such that
\begin{align}
A_* &= I - F'(F(x^*)) \\
\|A_*^{-1}[F'(F(x^*)) - F'(F(x))]\| &\leq \alpha \|F(x^*) - F(x)\|,
\end{align}
for all \(x, y, F(x) \in D\), and
\begin{align}
U(x^*, r^*) &\subseteq D,
\end{align}
where
\begin{align}
r^* &= \frac{2}{p + 2q}, \\
p &= \gamma(1 + 2\beta), \\
q &= \alpha \beta.
\end{align}
Then \(\{x_n\} (n \geq 0)\) generated by Stirling’s method (2) is well defined, remains in \(U(x^*, r^*)\) for all \(n \geq 0\), and converges to \(x^*\) provided that \(x_0 \in U(x^*, r^*)\). Moreover the following error bounds hold for all \(n \geq 0\):
\begin{align}
\|x_{n+1} - x^*\| &\leq \frac{p}{2} \frac{1}{1 - q \|x_n - x^*\|} \|x_n - x^*\|^2.
\end{align}

**Proof.** Let \(x \in U(x^*, r^*)\). Using (41), (42) we get
\begin{align}
\|A_*^{-1}[A_* - (I - F'(F(x)))\| &\leq \alpha \|F(x^*) - F(x)\| \leq \alpha \beta \|x - x^*\| \\
&< \alpha \beta r^* < 1 \quad \text{(by the choice of } r^*)
\end{align}
and \(F(x) \in U(x^*, r^*)\), since
\begin{align}
\|F(x) - x^*\| = \|F(x) - F(x^*)\| &\leq \beta \|x - x^*\| < \beta r^* \leq r^*.
\end{align}
Hence, by (48) and the Banach Lemma on invertible operators, \( I - F'(F(x)) \) is invertible, and

\[
\|(I - F'(F(x)))^{-1}A_\ast\| \leq \frac{1}{1 - q\|x - x^\ast\|}.
\]

By hypothesis \( x_0 \in U(x^\ast, r^\ast) \). Assume \( x_k \in U(x^\ast, r^\ast), k = 0, 1, \ldots, n. \)

As in (36) we obtain the approximation

\[
x_{k+1} - x^\ast = [A_k^{-1}A_\ast]^{-1}\{\int_0^1 [F'(\theta x_k + (1 - \theta)x^\ast) - F'(\theta F(x_k) + (1 - \theta)F(x_k))]\} (x_k - x^\ast) d\theta.
\]

By (51), (41)–(43) we get

\[
\|x_{k+1} - x^\ast\| \leq \frac{\gamma}{2} \|x_k - F(x_k)\| + \|F(x_k) - F(x^\ast)\| \|x_k - x^\ast\| \|x_k - x^\ast\|,
\]

\[
\|x_k - F(x_k)\| \leq \|x_k - x^\ast\| + \|F(x^\ast) - F(x_k)\| \leq (1 + \beta)\|x_k - x^\ast\|.
\]

Therefore we obtain

\[
\|x_{k+1} - x^\ast\| \leq \frac{\gamma (1 + \beta)}{2} \|x_k - x^\ast\| + \beta\|x_k - x^\ast\| \|x_k - x^\ast\| < \|x_k - x^\ast\|,
\]

which shows \( x_{k+1} \in U(x^\ast, r^\ast) \) and \( \lim_{k \to \infty} x_k = x^\ast. \)

That completes the proof of Theorem 3.

**Remark 2.** As noted in [3]–[6], [11] the local results obtained here can be used for projection methods such as Arnoldi’s, the generalized minimum residual method (GMRES), the generalized conjugate method (GCR), for combined Stirling’s finite difference projection methods and in connection with the mesh independence principle in order to develop the cheapest and most efficient mesh refinement strategies [4], [6].

**Remark 3.** The local results obtained here can also be used to solve (1), where \( F' \) satisfies the autonomous differential equation [3], [4], [7]

\[
F'(x) = T(F(x)),
\]

where \( T : X \to X \) is a known continuous operator. Since \( F'(F(x^\ast)) = T(F(F(x^\ast))) = T(F(0)) \), we can apply the results obtained here without actually knowing the fixed point \( x^\ast \) of \( F \).

We finally complete this study with a numerical example:

**Example 1.** Let \( X = D = U(0, 1) \) and define \( F \) on \( D \) by

\[
F(x) = e^x - x - 1.
\]
Using (40)–(43), (45), (46) and (55) we obtain (for $x^* = 0$)

$$
\alpha = e - 1, \quad \beta = e - 2, \quad \gamma = e
$$

and

$$
r^* = 0.219981153.
$$

The results obtained in [8] require

$$
\|F'(x)\| < 1 \quad \text{for all } x \in D.
$$

But (55) gives

$$
\|F'(x)\| \leq a = e - 1 > 1.
$$

Hence, these results cannot be used here. Note that Theorem 2 does not require $a \in [0, 1)$ but $a_0 \in [0, 1)$ where $a_0 \leq a$ (in general) and $a/a_0$ can be arbitrarily large [3], [4], [7]. Using

$$
\|F'(x^*)^{-1}[F'(x) - F'(y)]\| \leq w\|x - y\|,
$$

Rheinboldt [9] showed that the convergence radius for Newton’s method

$$
x_{n+1} = x_n - F'(x_n)^{-1}F(x_n) \quad (x_0 \in D, \ n \geq 0)
$$

is given by

$$
r = \frac{2}{3w}.
$$

However $w$ cannot be computed here since $F'(x^*)$ is not invertible.
