## ON THE ASYMPTOTIC BEHAVIOR OF SOME COUNTING FUNCTIONS, II <br> BY <br> WOLFGANG A. SCHMID (Graz)

#### Abstract

The investigation of the counting function of the set of integral elements, in an algebraic number field, with factorizations of at most $k$ different lengths gives rise to a combinatorial constant depending only on the class group of the number field and the integer $k$. In this paper the value of these constants, in case the class group is an elementary $p$-group, is estimated, and determined under additional conditions. In particular, it is proved that for elementary 2-groups these constants are equivalent to constants that are investigated in extremal graph theory.

1. Introduction. In this paper we investigate a class of invariants of finite abelian groups, arising from investigation of the asymptotic behavior of counting functions.

Let $K$ be a number field and $\mathcal{O}_{K}$ its ring of integers. For $a \in \mathcal{O}_{K}$ let $\mathrm{L}(a)$ denote its set of lengths, i.e., the set of $n \in \mathbb{N}_{0}$ such that $a=u_{1} \cdots u_{n}$ with atoms (irreducibles) $u_{1}, \ldots, u_{n} \in \mathcal{O}_{K}$. Let $k$ be a positive integer. The counting function

$$
\mathbf{G}_{k}(x)=\mid\{(a) \mid N(a) \leq x \text { and }|\mathrm{L}(a)| \leq k\} \mid
$$

was initially considered in [13] and later on by various authors (cf. [15, Chapter 9] and [17] for a recent result and further references). Note that this counting function is only interesting if $G$, the ideal class group of $K$, has at least three elements, since otherwise $\mathcal{O}_{K}$ is half-factorial, as proved in [2].

In [8] it was shown, by applying and generalizing results obtained in [11, 21, 22], that

$$
\mathbf{G}_{k}(x) \sim C x(\log x)^{-1+\mu(G) /|G|}(\log \log x)^{\psi_{k}(G)},
$$

where $C$ is a positive constant, $\mu(G)$ denotes the maximal cardinality of a half-factorial subset of $G$, and $\psi_{k}(G)$ depends on the structure of halffactorial subsets with maximal cardinality of $G$ (cf. Section 2, in particular

[^0]Definition 2.1). In particular, $\mu(G)$ and $\psi_{k}(G)$ depend just on $G$ and $k$, and not on the number field itself.

In this paper we will investigate $\psi_{k}(G)$. All our considerations will be carried out in the block monoid over $G$, a finite abelian group with $|G| \geq 3$, without making further use of the number field itself. The notion of block monoids was introduced in [14] to study combinatorial problems arising from the investigation of $\mathbf{G}_{k}(x)$ and other counting functions and is the main tool in the study of non-unique factorization in Krull monoids (cf. the references given in Section 2).

Not too much is known on the value of $\psi_{k}(G)$, in terms of invariants of $G$ such as rank or exponent. In $[21,22]$ the value of $\psi_{k}(G)$ is obtained for $|G| \in\{3,4\}$, and in [18] it is proved, motivated by investigations on the error term of $\mathbf{G}_{k}(x)$ in [17], that $\psi_{k}(G)>0$ for $k \geq 2$ and $\psi_{1}(G)>0$ for various types of groups. Moreover, in [22, P 1247] the problem whether $\left(\psi_{k}(G)\right)_{k=1}^{\infty}$ is an arithmetic progression is posed. Note that $B(k, G)$, as defined in [22], is not identical with $\psi_{k}(G)$; however, they are closely related and the present statement is equivalent to [22, P 1247] (cf. the considerations following Theorem 5.7 and [18, Introduction]).

In this paper we obtain good bounds for $\psi_{k}(G)$ in case $G$ is an elementary $p$-group, and under additional conditions even the precise value. More specifically, in Theorem 4.5 we determine $\psi_{1}(G)$ for elementary $p$-groups with $p \geq 3$ and even rank, and we determine $\psi_{k}(G)$ for $k>1$ under the additional condition that $p \geq \mathrm{r}(G) / 2$. In particular, this result shows that in this case $\left(\psi_{k}(G)\right)_{k=1}^{\infty}$ is an arithmetic progression (cf. Corollary 4.6). The case of odd rank, which we treat in Subsection 4.2 , seems to be more complicated and we just obtain lower bounds. For elementary 2 -groups we show that the problem of determining $\psi_{k}(G)$ is equivalent to a problem concerning edge disjoint cycles in graphs, and we use this equivalence and results on the graph-theoretic problem to prove $\psi_{1}(G)=\mathrm{r}(G)-1$ and to determine $\psi_{k}(G)$ up to a constant that is independent of $G$ (cf. Theorem 5.7). In particular, we show that these results imply that $\left(\psi_{k}(G)\right)_{k=1}^{\infty}$ is not always an arithmetic progression. However, in the cases we consider, it seems it is at least eventually an arithmetic progression.

In our investigations we apply results on the structure of half-factorial sets with maximal cardinality in $G$; such results are known for elementary $p$-groups, but so far only for very few other groups (cf. [7] for various results on half-factorial sets).
2. Preliminaries. Let $\mathbb{Z}$ denote the integers, $\mathbb{N}$ the positive integers, $\mathbb{N}_{0}$ the non-negative integers and $\mathbb{P}$ the prime numbers. For $m, n \in \mathbb{Z}$ let $[m, n]=\{z \in \mathbb{Z} \mid m \leq z \leq n\}$ and let $C_{n}$ denote a cyclic group with order $n$.

We summarize some notions and results concerning block monoids; for a detailed description and proofs we refer to the survey articles [3, 10]. Let $G$ be a finite abelian group and $G_{0} \subset G$ some subset. Then $\mathrm{r}(G)$ denotes the rank of $G,\left\langle G_{0}\right\rangle$ denotes the group generated by $G_{0}$, and $\mathcal{F}\left(G_{0}\right)$ denotes the multiplicatively written, free abelian monoid with basis $G_{0}$. An element $S=\prod_{i=1}^{l} g_{i}=\prod_{g \in G} g^{v_{g}(S)} \in \mathcal{F}\left(G_{0}\right)$ with $l \in \mathbb{N}_{0}$ and $g_{i} \in G_{0}$, respectively $\mathrm{v}_{g}(S) \in \mathbb{N}_{0}$, is called a sequence in $G_{0}$ (the identity element of $\mathcal{F}\left(G_{0}\right)$ is denoted by 1).

If $T \mid S$ (in $\mathcal{F}\left(G_{0}\right)$ ), then $T$ is called a subsequence of $S$ and $T^{-1} S$ denotes its co-divisor. Further $|S|=l$ is called the length, $\mathrm{k}(S)=\sum_{i=1}^{l} 1 / \operatorname{ord}\left(g_{i}\right)$ the cross number and $\sigma(S)=\sum_{i=1}^{l} g_{i}$ the sum of $S$.

A sequence $S$ is called a zero-sum sequence (or a block) if $\sigma(S)=0$, and it is called zero-sumfree if $\sigma(T) \neq 0$ for all subsequences $1 \neq T \mid S$.

The set $\mathcal{B}\left(G_{0}\right) \subset \mathcal{F}\left(G_{0}\right)$ of zero-sum sequences in $G_{0}$ is called the block monoid over $G_{0}$. It is atomic (in fact it is a Krull monoid) and its atoms $\mathcal{A}\left(G_{0}\right)$ are the minimal zero-sum sequences, i.e., zero-sum sequences such that every proper subsequence is zero-sumfree. Davenport's constant, D $(G)$, is defined as the maximal length of an atom in $G$. We only use the result that $\mathrm{D}\left(C_{p}\right)=p$ and $\mathrm{D}\left(C_{p}^{2}\right)=2 p-1$, where $C_{p}$ denotes a cyclic group with $p \in \mathbb{P}$ elements (cf. [6, 16]).

Let $B \in \mathcal{B}\left(G_{0}\right)$ and $B=\prod_{i=1}^{n} U_{i}$ with $U_{i} \in \mathcal{A}\left(G_{0}\right)$ a factorization of $B$ into atoms. Then $n$ is called the length of the factorization and $\mathrm{L}(B)=$ $\{n \mid B$ has a factorization of length $n\}$ is called the set of lengths of $B$. For $k \in \mathbb{N}_{0}$ we set $\mathcal{G}_{k}(G)=\{B \in \mathcal{B}(G)| | \mathrm{L}(B) \mid \leq k\}$. Note that $\mathrm{L}(1)=\{0\}$ and $\mathcal{G}_{0}(G)=\emptyset$.

A subset $G_{0} \subset G$ is called half-factorial if $\mathcal{B}\left(G_{0}\right)$ is a half-factorial monoid, i.e., $|\mathrm{L}(B)|=1$ for every $B \in \mathcal{B}\left(G_{0}\right)$, and $\mu(G)=\max \left\{\left|G_{0}\right| \mid G_{0} \subset\right.$ $G$ half-factorial\} denotes the maximal cardinality of a half-factorial subset of $G$. A set $G_{0}$ is half-factorial if and only if $\mathrm{k}(A)=1$ for each $A \in \mathcal{A}(G)$ (cf. [20, 21, 23]).

Let $G_{0} \subset G$ and $S \in \mathcal{F}\left(G \backslash G_{0}\right)$. Then

$$
\begin{aligned}
\Omega\left(G_{0}, S\right) & =S \mathcal{F}\left(G_{0}\right) \cap \mathcal{B}(G) \\
& =\left\{B \in \mathcal{B}(G) \mid \mathrm{v}_{g}(B)=\mathrm{v}_{g}(S) \text { for each } g \in G \backslash G_{0}\right\}
\end{aligned}
$$

Next we recall the central definition of this paper (cf. [8]).
Definition 2.1. Let $k \in \mathbb{N}$ and $G$ be a finite abelian group with $|G| \geq 3$. Then

$$
\begin{array}{r}
\psi_{k}(G)=\max \left\{|S| \mid G_{0} \subset G \text { half-factorial with }\left|G_{0}\right|=\mu(G)\right. \text { and } \\
\\
\left.S \in \mathcal{F}\left(G \backslash G_{0}\right) \text { with } \emptyset \neq \Omega\left(G_{0}, S\right) \subset \mathcal{G}_{k}(G)\right\}
\end{array}
$$

Throughout, let $G$ denote a finite abelian group with $|G| \geq 3$.
3. Some basic results. In this section we quote and establish some basic results on $\psi_{k}(G)$ and $\Omega\left(G_{0}, S\right)$. Parts of the results were initially obtained in $[9,21]$, however implicitly or in different notation. Proofs for all results mentioned can be found in [18, Section 4].

Let $G_{0} \subset G$ be a half-factorial subset with maximal cardinality. It follows immediately from the definition that $\Omega\left(G_{0}, S\right) \cdot \Omega\left(G_{0}, S^{\prime}\right) \subset \Omega\left(G_{0}, S S^{\prime}\right)$ for $S, S^{\prime} \in \mathcal{F}\left(G \backslash G_{0}\right)$. Moreover, $\left|\mathrm{L}\left(B B^{\prime}\right)\right| \geq|\mathrm{L}(B)|+\left|\mathrm{L}\left(B^{\prime}\right)\right|-1$ for $B, B^{\prime} \in \mathcal{B}(G)$ and therefore $\Omega\left(G_{0}, S\right) \not \subset \mathcal{G}_{k}(G)$ and $\Omega\left(G_{0}, S^{\prime}\right) \not \subset \mathcal{G}_{l}(G)$ implies $\Omega\left(G_{0}, S S^{\prime}\right) \not \subset \mathcal{G}_{k+l}(G)$ for $k, l \in \mathbb{N}_{0}$. This allows us to carry out investigations for special types of sequences and to transfer the results obtained to the general case. Of particular interest are sequences of length 1 , i.e., elements of the group. It is easy to see that $\Omega\left(G_{0}, g\right) \cap \mathcal{A}(G) \neq \emptyset$ for every $g \in\left\langle G_{0}\right\rangle \backslash G_{0}$. Moreover, if $k=\left|\mathrm{k}\left(\Omega\left(G_{0}, g\right) \cap \mathcal{A}(G)\right)\right|$, then $\Omega\left(G_{0}, g\right) \subset \mathcal{G}_{k}(G)$ and there exists some $B \in \Omega\left(G_{0}, g\right)$ with $|\mathrm{L}(B)|=k$ (cf. [18, Lemma 4.3]).

Lemma 3.1. Let $k \in \mathbb{N}$ and $G=G^{\prime} \oplus G^{\prime \prime}$ with $\left|G^{\prime}\right|,\left|G^{\prime \prime}\right| \geq 2$. Let $G_{0}^{\prime} \subset G^{\prime}$, $G_{0}^{\prime \prime} \subset G^{\prime \prime}, S^{\prime} \in \mathcal{F}\left(G^{\prime} \backslash G_{0}^{\prime}\right)$ and $S^{\prime \prime} \in \mathcal{F}\left(G^{\prime \prime} \backslash G_{0}^{\prime \prime}\right)$. Further let $G_{0}=G_{0}^{\prime} \cup G_{0}^{\prime \prime}$ and $S=S^{\prime} S^{\prime \prime} \in \mathcal{F}\left(G \backslash G_{0}\right)$.
(1) $\Omega\left(G_{0}^{\prime}, S^{\prime}\right) \cdot \Omega\left(G_{0}^{\prime \prime}, S^{\prime \prime}\right)=\Omega\left(G_{0}, S\right)$.
(2) If $\Omega\left(G_{0}^{\prime}, S^{\prime}\right) \subset \mathcal{G}_{k}\left(G^{\prime}\right)$ and $\Omega\left(G_{0}^{\prime \prime}, S^{\prime \prime}\right) \subset \mathcal{G}_{l}\left(G^{\prime \prime}\right)$ with $k, l \in \mathbb{N}_{0}$, then $\Omega\left(G_{0}, S\right) \subset \mathcal{G}_{k l}(G)$.
(3) Suppose $G_{0}^{\prime}$ and $G_{0}^{\prime \prime}$ are half-factorial, $g^{\prime} \in G_{0}^{\prime} \backslash\{0\}, g^{\prime \prime} \in G_{0}^{\prime \prime} \backslash\{0\}$ and $g=g^{\prime}+g^{\prime \prime}$. If $\emptyset \neq \Omega\left(G_{0}, S\right) \subset \mathcal{G}_{k}(G)$, then $\emptyset \neq \Omega\left(G_{0}, g S\right) \subset \mathcal{G}_{k}(G)$.
(4) Suppose $\mu(G)=\mu\left(G^{\prime}\right)+\mu\left(G^{\prime \prime}\right)-1$. Then
(a) $\psi_{k}(G) \geq 1$.
(b) $\psi_{k}(G) \geq \psi_{k}\left(G^{\prime}\right)+1$ if $\left|G^{\prime}\right| \geq 3$.
(c) $\psi_{k}(G) \geq \psi_{k}\left(G^{\prime}\right)+\psi_{1}\left(G^{\prime \prime}\right)+1$ if $\left|G^{\prime}\right|,\left|G^{\prime \prime}\right| \geq 3$.

Proof. (1) and (2). Clearly, $\Omega\left(G_{0}^{\prime}, S^{\prime}\right) \cdot \Omega\left(G_{0}^{\prime \prime}, S^{\prime \prime}\right) \subset \Omega\left(G_{0}, S\right)$. Let $B \in$ $\Omega\left(G_{0}, S\right)$. By definition of $G_{0}$ and $S$ we have $\mathrm{v}_{g}(B)=0$ for every $g \in$ $G \backslash\left(G^{\prime} \cup G^{\prime \prime}\right)$. Thus $B=B^{\prime} B^{\prime \prime}$ with $B^{\prime} \in \mathcal{F}\left(G^{\prime}\right)$ and $B^{\prime \prime} \in \mathcal{F}\left(G^{\prime \prime}\right)$. Since $G=G^{\prime} \oplus G^{\prime \prime}$, it follows that $B^{\prime}$ and $B^{\prime \prime}$ are zero-sum sequences. Moreover, every factorization of $B$ into atoms is the product of a factorization of $B^{\prime}$ and a factorization of $B^{\prime \prime}$. Thus $\mathrm{L}(B)=\mathrm{L}\left(B^{\prime}\right)+\mathrm{L}\left(B^{\prime \prime}\right)$ and $|\mathrm{L}(B)| \leq\left|\mathrm{L}\left(B^{\prime}\right)\right|$. $\left|\mathrm{L}\left(B^{\prime \prime}\right)\right|$.
(3) Note that $g \notin G^{\prime} \cup G^{\prime \prime}$. Let $C^{\prime} \in \Omega\left(G_{0}, S\right)$. Then

$$
C=g g^{\left(\operatorname{ord}\left(g^{\prime}\right)-1\right)} g^{\prime \prime\left(\operatorname{ord}\left(g^{\prime \prime}\right)-1\right)} C^{\prime} \in \Omega\left(G_{0}, g S\right)
$$

Thus it remains to prove the statement concerning the lengths of factorizations.

Let $B \in \Omega\left(G_{0}, g S\right)$ and let $B^{\prime}=g^{-1} g^{\prime} g^{\prime \prime} B \in \Omega\left(G_{0}, S\right)$. We assert that $1+\mathrm{L}(B) \subset \mathrm{L}\left(B^{\prime}\right)$. Since $\left|\mathrm{L}\left(B^{\prime}\right)\right| \leq k$, this proves the statement.

Let $B=\prod_{i=1}^{n} U_{i}$ be a factorization into atoms. Without restriction assume that $g \mid U_{1}$. Since $S^{\prime} \in \mathcal{F}\left(G^{\prime}\right)$ and $G_{0}^{\prime} \subset G^{\prime}$, respectively $S^{\prime \prime} \in \mathcal{F}\left(G^{\prime \prime}\right)$ and $G_{0}^{\prime \prime} \subset G^{\prime \prime}$, we have $U_{1}=\left(g^{\prime}+g^{\prime \prime}\right) F^{\prime} F^{\prime \prime}$ with zero-sumfree sequences $F^{\prime} \in \mathcal{F}\left(G^{\prime}\right)$ and $F^{\prime \prime} \in \mathcal{F}\left(G^{\prime \prime}\right)$. Thus $\sigma\left(F^{\prime}\right)=-g^{\prime}, \sigma\left(F^{\prime \prime}\right)=-g^{\prime \prime}$ and $\left(g^{\prime}+g^{\prime \prime}\right)^{-1} g^{\prime} g^{\prime \prime} U_{1}=\left(g^{\prime} F^{\prime}\right)\left(g^{\prime \prime} F^{\prime \prime}\right)\left(c f\right.$. [18, Lemma 4.2]). Since $g^{\prime} F^{\prime}$ and $g^{\prime \prime} F^{\prime \prime}$ are atoms, we conclude that $\left(g^{\prime} F^{\prime}\right)\left(g^{\prime \prime} F^{\prime \prime}\right) \prod_{i=2}^{n} U_{i}$ is a factorization of $B^{\prime}$ into atoms and $1+n \in \mathrm{~L}\left(B^{\prime}\right)$.
(4) Suppose $G_{0}^{\prime}$ and $G_{0}^{\prime \prime}$ are half-factorial with $\left|G_{0}^{\prime}\right|=\mu\left(G^{\prime}\right)$ and $\left|G_{0}^{\prime \prime}\right|=$ $\mu\left(G^{\prime \prime}\right)$. We have $\left|G_{0}\right|=\mu(G)$. Since $\mu\left(G^{\prime}\right), \mu\left(G^{\prime \prime}\right) \geq 2$ there exist $g^{\prime} \in G_{0}^{\prime} \backslash\{0\}$ and $g^{\prime \prime} \in G_{0}^{\prime \prime} \backslash\{0\}$. We set $g=g^{\prime}+g^{\prime \prime}$. We note that $\emptyset \neq \Omega\left(G_{0}, 1\right) \subset \mathcal{G}_{1}(G)$ and apply (3) with $S=1$. This implies $\emptyset \neq \Omega\left(G_{0}, g\right) \subset \mathcal{G}_{1}(G)$, which proves (a).

If $\left|G^{\prime}\right| \geq 3$, then suppose there exists a sequence $S^{\prime} \in \mathcal{F}\left(G^{\prime} \backslash G_{0}^{\prime}\right)$ with $\emptyset \neq \Omega\left(G_{0}^{\prime}, S^{\prime}\right) \subset \mathcal{G}_{k}\left(G^{\prime}\right)$ and $\left|S^{\prime}\right|=\psi_{k}\left(G^{\prime}\right)$. Since $\emptyset \neq \Omega\left(G_{0}^{\prime \prime}, 1\right) \subset \mathcal{G}_{1}\left(G^{\prime \prime}\right)$ we apply (1) with $S^{\prime \prime}=1$ and obtain $\emptyset \neq \Omega\left(G_{0}, S^{\prime}\right) \subset \mathcal{G}_{k}(G)$. Applying (3) we obtain $\emptyset \neq \Omega\left(G_{0}, g S^{\prime}\right) \subset \mathcal{G}_{k}(G)$. Thus $\psi_{k}(G) \geq\left|g S^{\prime}\right|=1+\psi_{k}\left(G^{\prime}\right)$, which proves (b).

If in addition $\left|G^{\prime \prime}\right| \geq 3$, then suppose there exists a sequence $S^{\prime \prime} \in \mathcal{F}\left(G^{\prime \prime} \backslash\right.$ $\left.G_{0}^{\prime \prime}\right)$ with $\emptyset \neq \Omega\left(G_{0}^{\prime \prime}, S^{\prime \prime}\right) \subset \mathcal{G}_{1}\left(G^{\prime \prime}\right)$ and $\left|S^{\prime \prime}\right|=\psi_{1}\left(G^{\prime \prime}\right)$. Again by (1) and (3) we obtain $\emptyset \neq \Omega\left(G_{0}, g S^{\prime} S^{\prime \prime}\right) \subset \mathcal{G}_{m}(G)$, which proves (c).

In [9, Proposition 5] it was proved that if $G=G^{\prime} \oplus G^{\prime \prime}$, then $\mu(G) \geq$ $\mu\left(G^{\prime}\right)+\mu\left(G^{\prime \prime}\right)-1$. Moreover, there are examples where equality holds as well as examples where equality does not hold (cf. the results quoted in Section 4). Thus $\mu(G)=\mu\left(G^{\prime}\right)+\mu\left(G^{\prime \prime}\right)-1$ is a non-trivial condition. In particular, the statement of Lemma 3.1(4) is not true without this condition as Theorem 4.5 and Proposition 4.9 will show.

Lemma 3.2. Let $k, l \in \mathbb{N}$. If each half-factorial set $G_{0} \subset G$ with $\left|G_{0}\right|=$ $\mu(G)$ generates $G$, then

$$
\psi_{k+l}(G) \leq \psi_{k}(G)+\psi_{l}(G)+1
$$

Proof. Assume to the contrary that $\psi_{k+l}(G) \geq \psi_{k}(G)+\psi_{l}(G)+2$. Let $G_{0} \subset G$ be half-factorial with $\left|G_{0}\right|=\mu(G)$ and $S \in \mathcal{F}\left(G \backslash G_{0}\right)$ be such that $\emptyset \neq \Omega\left(G_{0}, S\right) \subset \mathcal{G}_{k+l}(G)$ and $|S|=\psi_{k+l}(G)$. By assumption there exist $S^{\prime}, S^{\prime \prime} \in \mathcal{F}\left(G \backslash G_{0}\right)$ such that $S=S^{\prime} S^{\prime \prime},\left|S^{\prime}\right|>\psi_{k}(G)$ and $\left|S^{\prime \prime}\right|>\psi_{l}(G)$. Since $\left\langle G_{0}\right\rangle=G$, there exist blocks $B^{\prime} \in \Omega\left(G_{0}, S^{\prime}\right)$ and $B^{\prime \prime} \in \Omega\left(G_{0}, S^{\prime \prime}\right)$ such that $\left|\mathrm{L}\left(B^{\prime}\right)\right|>k$ and $\left|\mathrm{L}\left(B^{\prime \prime}\right)\right|>l$. Thus $B=B^{\prime} B^{\prime \prime} \in \Omega\left(G_{0}, S\right)$ and $|\mathrm{L}(B)| \geq\left|\mathrm{L}\left(B^{\prime}\right)\right|+\left|\mathrm{L}\left(B^{\prime \prime}\right)\right|-1 \geq k+1+l+1-1>k+l$, a contradiction.

In this paper we only deal with groups $G$ where every half-factorial subset of maximal cardinality generates $G$, namely with elementary $p$-groups and cyclic groups with prime power order (in [7, Proposition 3.5] it is proved that this holds true for elementary and cyclic groups). Thus for the groups
we consider the condition in Lemma 3.2 is always fulfilled and moreover we always have $\Omega\left(G_{0}, S\right) \neq \emptyset$ if $G_{0} \subset G$ is half-factorial with maximal cardinality and $S \in \mathcal{F}\left(G \backslash G_{0}\right)$.

## 4. $\psi_{k}(G)$ for elementary $p$-groups

4.1. Groups with even rank. For elementary p-groups with even rank the value of $\mu(G)$ and the structure of half-factorial sets with maximal cardinality are known. We use this to investigate $\psi_{k}(G)$ for these groups.

Proposition 4.1 ([9, 19]). Let $G$ be an elementary p-group with even rank $\mathrm{r}(G)=2 r$. Then $\mu(G)=1+r p$, and $G_{0} \subset G$ is half-factorial with $\left|G_{0}\right|=\mu(G)$ if and only if there exists a basis $\left\{e_{1}, e_{1}^{\prime}, \ldots, e_{r}, e_{r}^{\prime}\right\}$ of $G$ such that

$$
G_{0}=\{0\} \cup \bigcup_{i=1}^{r}\left\{j e_{i}+e_{i}^{\prime} \mid j \in[0, p-1]\right\}
$$

Proof. The result on $\mu(G)$ and the "if" part were proved in [9, Theorem 8], and the "only if" part in [19, Theorem 3.1]. Note that in both papers the sets are described in a different basis, namely $\left\{e_{1}+e_{1}^{\prime}, e_{1}^{\prime}, \ldots\right.$, $\left.e_{r}+e_{r}^{\prime}, e_{r}^{\prime}\right\}$.

For our purpose it is particularly interesting that for a given group all half-factorial subsets of maximal cardinality are equal up to automorphisms of the group. Thus it suffices to investigate $\Omega\left(G_{0}, \cdot\right)$ for one fixed half-factorial set $G_{0} \subset G$ with maximal cardinality.

Note that for $p=2$ the description of the half-factorial sets is not natural, since for $p=2$ the set $G_{0} \backslash\{0\}$ is independent. In Section 5 we will separately investigate elementary 2 -groups (not necessarily with even rank). Thus whenever convenient we will assume $p \neq 2$.

Throughout the whole subsection we will use the following notations. Let $G$ be an elementary $p$-group with $\operatorname{rank} \mathrm{r}(G)=2 r$ and $\left\{e_{1}, e_{1}^{\prime}, \ldots, e_{r}, e_{r}^{\prime}\right\} \subset G$ a basis of $G$. Further let

$$
G_{0}=\{0\} \cup \bigcup_{i=1}^{r}\left\{j e_{i}+e_{i}^{\prime} \mid j \in[0, p-1]\right\}
$$

be a half-factorial set with $\left|G_{0}\right|=\mu(G)$. For $i \in[1, r]$ let $\pi_{i}$ denote the projection on $\left\langle e_{i}\right\rangle, \pi_{i}^{\prime}$ the projection on $\left\langle e_{i}^{\prime}\right\rangle$, and

$$
G_{0}^{i}=\left(\pi_{i}+\pi_{i}^{\prime}\right)\left(G_{0}\right)=\{0\} \cup\left\{j e_{i}+e_{i}^{\prime} \mid j \in[0, p-1]\right\}
$$

We start with a technical lemma on cross numbers of certain atoms. It is of interest, since the number of different values of the cross numbers of the atoms in $\Omega\left(G_{0}, g\right)$ determines the maximal cardinality of the sets of lengths of blocks in $\Omega\left(G_{0}, g\right)$ (cf. Section 3 and [18, Lemma 4.3]).

Lemma 4.2. Let $g=\sum_{i=1}^{r} a_{i} e_{i}+b_{i} e_{i}^{\prime} \notin G_{0}$ with $a_{i}, b_{i} \in[0, p-1]$ and $A \in \Omega\left(G_{0}, g\right) \cap \mathcal{A}(G)$. Then

$$
\mathrm{k}(A)=\frac{1}{p}+\left|I_{1}\right| \frac{p-1}{p}+\left|I_{2}\right|+\left|I_{3}\right|-\frac{c_{g}}{p}+m_{A}
$$

where $I_{1}=\left\{i \in[1, r] \mid b_{i}=1\right\}, I_{2}=\left\{i \in[1, r] \mid b_{i}=0\right.$ and $\left.a_{i} \neq 0\right\}$, $I_{3}=\left\{i \in[1, r] \mid b_{i} \notin[0,1]\right\}, c_{g}=\sum_{i \in I_{3}} b_{i}$ and $m_{A} \in\left[0,\left|I_{3}\right|\right]$. Moreover,

$$
\left|\mathrm{k}\left(\Omega\left(G_{0}, g\right) \cap \mathcal{A}(G)\right)\right|=1+\left|\left\{i \in[1, r] \mid b_{i} \notin[0,1]\right\}\right| .
$$

Proof. Let $B \in \Omega\left(G_{0}, g\right)$. Then $B=g 0^{v} \prod_{i=1}^{r} S_{i}$ with uniquely determined $v \in \mathbb{N}_{0}$ and $S_{i} \in \mathcal{F}\left(G_{0}^{i} \backslash\{0\}\right)$ for each $i \in[1, r]$. We note that $B \in \mathcal{A}(G)$ if and only if $v=0$ and $\left(a_{i} e_{i}+b_{i} e_{i}^{\prime}\right) S_{i}$ is an atom for each $i \in[1, r]$. Thus it suffices to investigate each component separately.

For each $i \in[1, r]$ let $g_{i}=\left(\pi_{i}+\pi_{i}^{\prime}\right)(g)=a_{i} e_{i}+b_{i} e_{i}^{\prime}$ and $F_{i} \in \mathcal{F}\left(G_{0}^{i}\right)$ be such that $A=g \prod_{i=1}^{r} F_{i}$. Then $g_{i} F_{i}$ is an atom for each $i \in[1, r]$. If $b_{i}=1$ or $a_{i}=b_{i}=0$, then $\left\{g_{i}\right\} \cup G_{0}^{i}$ is half-factorial. Consequently, $\mathrm{k}\left(g_{i} F_{i}\right)=1$, and $\mathrm{k}\left(F_{i}\right)=(p-1) / p$ if $b_{i}=1$, while $\mathrm{k}\left(F_{i}\right)=0$ if $a_{i}=b_{i}=0$. If $b_{i}=0$ and $a_{i} \neq 0$, then $F_{i} \neq 1$ and $\left|F_{i}\right| e_{i}^{\prime}=0$. Since $F_{i}$ is zero-sumfree and $\mathrm{D}\left(C_{p}^{2}\right)=2 p-1$, it follows that $\left|F_{i}\right|<2 p-1$ and therefore $\left|F_{i}\right|=p$ and $\mathrm{k}\left(F_{i}\right)=1$.

Suppose $b_{i} \notin[0,1]$. Since $\left(b_{i}+\left|F_{i}\right|\right) e_{i}^{\prime}=0$ and $\left|F_{i}\right| \in[1,2 p-2]$, we infer that $\left|F_{i}\right| \in\left\{p-b_{1}, 2 p-b_{1}\right\}$.

Let $I_{1}, I_{2}, I_{3}$ and $c_{g}$ be as in the formulation of the lemma and $I_{4}=$ $\left\{i \in I_{3} \mid \mathrm{k}\left(F_{i}\right)=2 p-b_{i}\right\}$. Then

$$
\mathrm{k}(A)=\frac{1}{\operatorname{ord}(g)}+\sum_{i=1}^{r} \mathrm{k}\left(F_{i}\right)=\frac{1}{p}+\left|I_{1}\right| \frac{p-1}{p}+\left|I_{2}\right|+\left|I_{3}\right|-\frac{c_{g}}{p}+\left|I_{4}\right|
$$

and clearly $\left|I_{4}\right| \in\left[0,\left|I_{3}\right|\right]$, which proves the first part of the lemma and implies immediately that $\left|\mathrm{k}\left(\Omega\left(G_{0}, g\right) \cap \mathcal{A}(G)\right)\right| \leq 1+\left|\left\{i \in[1, r] \mid b_{i} \notin[0,1]\right\}\right|$.

To prove the remaining part, it suffices to verify that for each $i \in I_{3}$ there are sequences $F_{i}^{\prime}, F_{i}^{\prime \prime} \in \mathcal{F}\left(G_{0}^{i}\right)$ such that $g_{i} F_{i}^{\prime}, g_{i} F_{i}^{\prime \prime} \in \mathcal{A}(G), \mathrm{k}\left(F_{i}^{\prime}\right)=p-b_{i}$ and $\mathrm{k}\left(F_{i}^{\prime \prime}\right)=2 p-b_{i}$. The sequences $F_{i}^{\prime}=\left(-a_{i} e_{i}+e_{i}^{\prime}\right) e_{i}^{\prime p-b_{i}-1}$ and

$$
F_{i}^{\prime \prime}= \begin{cases}\left(e_{i}+e_{i}^{\prime}\right)^{p-b_{i}+1}\left(\left(-b_{i}+1\right) e_{i}+e_{i}^{\prime}\right)^{p-1} & \text { if } a_{i}=0 \\ e_{i}^{\prime p-b_{i}+1}\left(a_{i} e_{i}+e_{i}^{\prime}\right)^{p-1} & \text { if } a_{i} \neq 0\end{cases}
$$

have these properties.
In the following lemma we derive a lower bound for $\psi_{k}(G)$. In Theorem 4.5 we will see that equality holds in several cases.

Lemma 4.3. Let $k \in \mathbb{N}$. Then $\psi_{k}(G) \geq(k-1+r) p-1$.
Proof. We proceed by induction on $r$. Let $r=1$. We set $S=e_{1}^{k p-1}$ and show that $\Omega\left(G_{0}, S\right) \subset \mathcal{G}_{k}(G)$. We start with an investigation of the
cross numbers of the atoms in $\left\{e_{1}\right\} \cup G_{0}$. For ease of notation we omit the subscript 1.

Let $A \in \mathcal{A}\left(\{e\} \cup G_{0}\right)$. If $\mathrm{v}_{e}(A) \in\{0, p\}$, then $\mathrm{k}(A)=1$. Suppose $A=e^{v} F$ with $v \in[1, p-1]$ and $F \in \mathcal{F}\left(G_{0}\right)$. Clearly, $F \neq 1$ and $F$ is zero-sumfree, thus $1 \leq|F| \leq 2 p-2$ as in Lemma 4.2. Since $|F| e^{\prime}=0$, we obtain $|F|=p$ and $\mathrm{k}(A)=1+\mathrm{v}_{e}(A) / p$.

Let $B \in \Omega\left(G_{0}, S\right)$ and $B=\left(e^{p}\right)^{m} \prod_{i=1}^{l} U_{i}$ be a factorization into atoms, where $\mathrm{v}_{e}\left(U_{i}\right)<p$ for each $i \in[1, l]$. Clearly, $m \in[0, k-1]$. It follows that

$$
\mathrm{k}(B)=m+\sum_{i=1}^{l} \frac{p+\mathrm{v}_{e}\left(U_{i}\right)}{p}=m+l+\frac{\mathrm{v}_{e}(B)-p m}{p}=l+\frac{k p-1}{p}
$$

Thus $l=\mathrm{k}(B)-k+1 / p$ is determined by $B, \mathrm{~L}(B) \subset l+[0, k-1]$ and $|\mathrm{L}(B)| \leq k$.

Let $r \geq 2$ and $G=G^{\prime} \oplus G^{\prime \prime}$ with $\mathrm{r}\left(G^{\prime}\right)=2(r-1)$ and $\mathrm{r}\left(G^{\prime \prime}\right)=2$. By induction hypothesis we have $\psi_{k}\left(G^{\prime}\right) \geq(k-1+r-1) p-1$ and $\psi_{1}\left(G^{\prime \prime}\right) \geq p-1$. By Lemma 3.1(4) we get $\psi_{k}(G) \geq(k-1+r-1) p-1+p-1+1=$ $(k-1+r) p-1$.

Next we prove a proposition that will be needed to establish an upper bound for $\psi_{k}(G)$. By $\sum_{i=1}^{r} G_{0}^{i}$ we denote, as usual, the set of elements $\sum_{i=1}^{r} g_{i}$ with $g_{i} \in G_{0}^{i}$ for each $i \in[1, r]$.

Proposition 4.4. Let $p \geq 3$. Then $\Omega\left(G_{0}, S\right) \not \subset \mathcal{G}_{1}(G)$ for each of the following choices of $S \in \mathcal{F}\left(G \backslash G_{0}\right)$ :
(1) $S=g \in G \backslash\left(\left\langle e_{1}, \ldots, e_{r}\right\rangle+\sum_{i=1}^{r} G_{0}^{i}\right)$.
(2) $S \in \mathcal{F}\left(\left(\left\langle e_{1}, \ldots, e_{r}\right\rangle+\sum_{i=1}^{r} G_{0}^{i}\right) \backslash \sum_{i=1}^{r} G_{0}^{i}\right)$ such that $\left(\pi_{m}+\pi_{m}^{\prime}\right)(S) \in$ $\mathcal{A}\left(\left\langle e_{m}\right\rangle \backslash\{0\}\right)$ for some $m \in[1, r]$.
(3) $S=g h$ with $g, h \in\left\langle e_{1}, \ldots, e_{r}\right\rangle+\sum_{i=1}^{r} G_{0}^{i}$ such that $\pi_{j}^{\prime}(g)=\pi_{j}^{\prime}(h)=$ $e_{j}^{\prime}$ and $\pi_{m}^{\prime}(g)=\pi_{m}^{\prime}(h)=e_{m}^{\prime}$ for distinct $j, m \in[1, r]$.
(4) $S=\prod_{j=1}^{s} g_{j} \in \mathcal{F}\left(\left\langle e_{1}, \ldots, e_{r}\right\rangle+\sum_{i=1}^{r} G_{0}^{i}\right)$ with $s \geq 3$ and $I_{j}=\{i \in$ $\left.[1, r] \mid \pi_{i}^{\prime}\left(g_{j}\right)=e_{i}^{\prime}\right\}$ such that for every $J \subset[1, s]$ with $|J| \geq 2$,

$$
\left|\bigcap_{j \in J} I_{j}\right|= \begin{cases}1 & \text { if } J=\left\{j, j^{\prime}\right\} \text { and } j-j^{\prime} \equiv \pm 1 \bmod s \\ 0 & \text { otherwise }\end{cases}
$$

Proof. (1) By Lemma 4.2 we have

$$
\left|\mathrm{k}\left(\Omega\left(G_{0}, g\right) \cap \mathcal{A}(G)\right)\right|>1
$$

since $\left\{g=\sum_{i=1}^{r} a_{i} e_{i}+b_{i} e_{i}^{\prime} \mid b_{i} \in[0,1]\right\}=\left\langle e_{1}, \ldots, e_{r}\right\rangle+\sum_{i=1}^{r} G_{0}^{i}$. This implies $\Omega\left(G_{0}, S\right) \not \subset \mathcal{G}_{1}(G)$.
(2) Let $S=\prod_{j=1}^{l} g_{j}$. For each $j \in[1, l]$ there exists some atom $A_{j} \in$ $\Omega\left(G_{0}, g_{j}\right)$. By Lemma 4.2 and its proof we get $A_{j}=g_{j} F_{j} F_{j}^{\prime}$ with $F_{j} \in$ $\mathcal{F}\left(G_{0}^{m}\right), F_{j}^{\prime} \in \mathcal{F}\left(G_{0} \backslash G_{0}^{m}\right)$ and $\left|F_{j}\right|=p$, since $\pi_{m}^{\prime}\left(g_{j}\right)=0$ and $\pi_{m}\left(g_{j}\right) \neq 0$.

We consider the block $B=\prod_{j=1}^{l} A_{j} \in \Omega\left(G_{0}, S\right)$. Clearly, $l \in \mathrm{~L}(B)$. Since $\sigma\left(\left(\pi_{m}+\pi_{m}^{\prime}\right)(S)\right)=0$, we have $\sigma\left(\prod_{j=1}^{l} F_{j}\right)=0$. Since $F_{j} \in \mathcal{F}\left(G_{0}^{m}\right)$ and $G_{0}^{m}$ is half-factorial, we obtain $\{l\}=\mathrm{L}\left(\prod_{j=1}^{l} F_{j}\right)$. Consequently, $B=$ $\left(\prod_{j=1}^{l} F_{j}\right)\left(\prod_{j=1}^{l} g_{j} F_{j}^{\prime}\right)$ and $l+\mathrm{L}\left(\prod_{j=1}^{l} g_{j} F_{j}^{\prime}\right) \subset \mathrm{L}(B)$. Clearly, $\prod_{j=1}^{l} g_{j} F_{j}^{\prime} \neq 1$ and thus $\mathrm{L}\left(\prod_{j=1}^{l} g_{j} F_{j}^{\prime}\right) \neq\{0\}$, which implies $|\mathrm{L}(B)|>1$.
(3) Suppose there exist $A, A^{\prime} \in \Omega\left(G_{0}, S\right) \cap \mathcal{A}(G)$ with $\mathrm{k}(A) \neq \mathrm{k}\left(A^{\prime}\right)$. Then there exists some $B \in \Omega\left(G_{0}, S\right)$ such that $A \mid B$ and $A^{\prime} \mid B$, for example $S^{-1} A A^{\prime} T$ with $T \in \mathcal{F}\left(G_{0}\right)$ and $\sigma(T)=\sigma(S)$. This implies

$$
\left\{1+\mathrm{k}(B)-\mathrm{k}(A), 1+\mathrm{k}(B)-\mathrm{k}\left(A^{\prime}\right)\right\} \subset \mathrm{L}(B)
$$

and thus $|\mathrm{L}(B)| \geq 2$. Consequently, it suffices to show that there exist atoms $A, A^{\prime} \in \Omega\left(G_{0}, S\right)$ with $\mathrm{k}(A) \neq \mathrm{k}\left(A^{\prime}\right)$.

Without restriction let $j=1$ and $m=2$. We have $g=a_{1} e_{1}+e_{1}^{\prime}+a_{2} e_{2}+$ $e_{2}^{\prime}+g_{1}$ and $h=a_{1}^{\prime} e_{1}+e_{1}^{\prime}+a_{2}^{\prime} e_{2}+e_{2}^{\prime}+h_{1}$ with $a_{1}, a_{2}, a_{1}^{\prime}, a_{2}^{\prime} \in[0, p-1]$ and $h_{1}, g_{1} \in\left\langle e_{3}, \ldots, e_{r}^{\prime}\right\rangle$.

Let $F_{2}=\left(-\left(a_{2}+a_{2}^{\prime}\right) e_{2}+e_{2}^{\prime}\right) e_{2}^{\prime p-3}$ and $F \in \mathcal{F}\left(G_{0}\right)$ be zero-sumfree with $\sigma(F)=-g_{1}-h_{1}$. Further let $F_{1}=\left(-\left(a_{1}+a_{1}^{\prime}\right) e_{1}+e_{1}^{\prime}\right) e_{1}^{p-3}$ and

$$
F_{1}^{\prime}= \begin{cases}\left(e_{1}+e_{1}^{\prime}\right)^{p-1}\left(-e_{1}+e_{1}^{\prime}\right)^{p-1} & \text { if } a_{1}+a_{1}^{\prime} \equiv 0 \bmod p \\ e_{1}^{\prime p-1}\left(\left(a_{1}+a_{1}^{\prime}\right) e_{1}+e_{1}^{\prime}\right)^{p-1} & \text { if } a_{1}+a_{1}^{\prime} \not \equiv 0 \bmod p\end{cases}
$$

Then $A=g h F F_{2} F_{1}$ and $A^{\prime}=g h F F_{2} F_{1}^{\prime}$ are atoms, elements of $\Omega\left(G_{0}, S\right)$ and $\mathrm{k}(A) \neq \mathrm{k}\left(A^{\prime}\right)$.

This construction is similar to the one used in Lemma 4.2. Note that $\left(a_{1} e_{1}+e_{1}^{\prime}\right)\left(a_{1}^{\prime} e_{1}+e_{1}^{\prime}\right) F_{1}^{\prime}$ is not an atom but the product of two atoms, where $a_{1} e_{1}+e_{1}^{\prime}$ divides one atom and $a_{1}^{\prime} e_{1}+e_{1}^{\prime}$ divides the other. However, due to the choice of $F_{2}$, we conclude that $A^{\prime}$ cannot be factorized into two atoms such that $g$ divides one and $h$ the other.
(4) Let $\left\{i_{1}\right\}=I_{s} \cap I_{1}$ and $\left\{i_{j}\right\}=I_{j-1} \cap I_{j}$ for each $j \in[2, s]$. Clearly, $\left|\left\{i_{1}, \ldots, i_{s}\right\}\right|=s$ and without restriction we assume $i_{j}=j$ for each $j \in[1, s]$. Similarly to the construction in the proof of (3) we assert that there exist $A, A^{\prime} \in \Omega\left(G_{0}, S\right) \cap \mathcal{A}(G)$ with $\mathrm{k}(A) \neq \mathrm{k}\left(A^{\prime}\right)$. For $j \in[1, s]$ let $c_{j} \in[0, p-1]$ be such that $c_{j} e_{j}=-\pi_{j}(\sigma(S))$ and $F_{j}=\left(c_{j} e_{j}+e_{j}^{\prime}\right) e_{j}^{\prime p-3}$. Further let

$$
F_{1}^{\prime}= \begin{cases}\left(e_{1}+e_{1}^{\prime}\right)^{p-1}\left(-e_{1}+e_{1}^{\prime}\right)^{p-1} & \text { if } c_{1}=0 \\ e_{1}^{p-1}\left(-c_{1} e_{1}+e_{1}^{\prime}\right)^{p-1} & \text { if } c_{1} \neq 0\end{cases}
$$

and $F \in \mathcal{F}\left(G_{0}\right)$ be zero-sumfree with $\sigma(F)=-\sum_{m=s+1}^{r}\left(\pi_{m}+\pi_{m}^{\prime}\right)(\sigma(S))$. Note that $F \in \mathcal{F}\left(\left\langle e_{s+1}, \ldots, e_{r}^{\prime}\right\rangle\right)$. We verify that

$$
A=F_{1} S F \prod_{j=2}^{l} F_{j} \quad \text { and } \quad A^{\prime}=F_{1}^{\prime} S F \prod_{j=2}^{l} F_{j}
$$

are atoms in $\Omega\left(G_{0}, S\right)$ with different cross numbers. That $\mathrm{k}(A) \neq \mathrm{k}\left(A^{\prime}\right)$ is obvious and that $\sigma(A)=\sigma\left(A^{\prime}\right)=0$ can be checked easily, thus by construction $A, A^{\prime} \in \Omega\left(G_{0}, S\right)$. It remains to show that $A, A^{\prime}$ are atoms. We do this just for $A^{\prime}$, since for $A$ one can argue analogously. Suppose $A^{\prime}=B_{1} B_{2}$ with $B_{1}, B_{2} \in \mathcal{B}(G) \backslash\{1\}$. Without restriction assume that $g_{1} \mid B_{1}$. Since $\pi_{2}^{\prime}\left(g_{1}\right)=e_{2}^{\prime}$ and $\pi_{2}^{\prime}(g) \neq 0$ if and only if $g \mid g_{1} g_{2} F_{2}$, we have $g_{1} g_{2} F_{2} \mid B_{1}$. The same way, since $\pi_{3}^{\prime}\left(g_{2}\right)=e_{3}^{\prime}$, we obtain $g_{2} g_{3} F_{3} \mid B_{1}$. Repeating this construction, we get $g_{j} \mid B_{1}$ for each $j \in[1, s]$ and thus $\prod_{j=1}^{s} g_{j} \mid B_{1}$. Consequently, $B_{2} \mid F \prod_{j=1}^{s} F_{j}$. By construction $F \prod_{j=1}^{s} F_{j}$ is zero-sumfree, a contradiction.

Note that (1), (2), and (3), the latter with a slightly different proof, hold for $p=2$ as well. Moreover, in Lemma 5.4 we obtain a result similar to (4) for elementary 2 -groups.

Theorem 4.5. Let $p \geq 3, k \in \mathbb{N}$ and $G$ be an elementary p-group with $r(G)=2 r$. Then

$$
(k-1+r) p-1 \leq \psi_{k}(G) \leq r p-1+(k-1) \max \{p, r\}
$$

In particular, $\psi_{1}(G)=r p-1$ and if $p \geq r$, then $\psi_{k}(G)=(k-1+r) p-1$.
Proof. The lower bound was obtained in Lemma 4.3. It suffices to show $\psi_{k}(G) \leq r p-1+(k-1) \max \{p, r\}$, since the other statements follow immediately. We will prove that (for $G_{0} \subset G$ half-factorial with $\left|G_{0}\right|=\mu(G)$ ) if $S \in \mathcal{F}\left(G \backslash G_{0}\right)$ with $|S| \geq r p+(k-1) \max \{p, r\}$, then $\Omega\left(G_{0}, S\right) \not \subset \mathcal{G}_{k}(G)$.

We proceed by induction on $k$. Let $k=1$ and $S=\prod_{i=1}^{l} g_{i} \in \mathcal{F}\left(G \backslash G_{0}\right)$ with $l \geq r p$. We need to show that $\Omega\left(G_{0}, S\right) \not \subset \mathcal{G}_{1}(G)$. We will prove a slightly more general statement that will be needed in the rest of the proof: there exists a subsequence $R \mid S$ with $|R| \leq \max \{p, r\}$ such that $\Omega\left(G_{0}, R\right)$ $\not \subset \mathcal{G}_{1}(G)$.

This is done in four steps. In each step we use the relevant part of Proposition 4.4.

STEP 1. Suppose there exists some $g \mid S$ with $g \in G \backslash\left(\left\langle e_{1}, \ldots, e_{r}\right\rangle+\right.$ $\left.\sum_{i=1}^{r} G_{0}^{i}\right)$. Then by Proposition $4.4(1)$ we have $\Omega\left(G_{0}, g\right) \not \subset \mathcal{G}_{1}(G)$. We set $R=g$ and are done. Thus we assume without restriction $S \in \mathcal{F}\left(\left\langle e_{1}, \ldots, e_{r}\right\rangle\right.$ $\left.+\sum_{i=1}^{r} G_{0}^{i}\right)$.

Step 2. Let $S^{\prime} \mid S$ denote the subsequence consisting of the elements $g \mid S$ for which there exists some $j_{g} \in[1, r]$ with $\left(\pi_{j_{g}}+\pi_{j_{g}}^{\prime}\right)(g) \in\left\langle e_{j}\right\rangle \backslash\{0\}$. Suppose $\left|S^{\prime}\right| \geq r(p-1)+1$. Then there exists some $m \in[1, r]$ and a sequence $S^{\prime \prime} \mid S^{\prime}$ with $\left|S^{\prime \prime}\right| \geq p$ such that $\left(\pi_{m}+\pi_{m}^{\prime}\right)\left(S^{\prime \prime}\right) \in \mathcal{F}\left(\left\langle e_{m}\right\rangle \backslash\{0\}\right)$. Since $\left|S^{\prime \prime}\right| \geq$ $\left|\left\langle e_{m}\right\rangle\right|$, there exists some $A \mid S^{\prime \prime}$ with $\left(\pi_{m}+\pi_{m}^{\prime}\right)(A) \in \mathcal{A}\left(\left\langle e_{m}\right\rangle \backslash\{0\}\right)$. By Proposition $4.4(2)$ this implies $\Omega\left(G_{0}, A\right) \not \subset \mathcal{G}_{1}(G)$. Since $|A| \leq p$, we set $R=A$. We assume that $\left|S^{\prime}\right| \leq r(p-1)$ and consequently $\left|S^{\prime-1} S\right| \geq r$.

STEP 3. Let $T=S^{\prime-1} S$ and for each $g \mid T$ let $I_{g}=\left\{i \in[1, r] \mid \pi_{i}^{\prime}(g)\right.$ $\left.=e_{i}^{\prime}\right\}$. It follows that $\left|I_{g}\right| \geq 2$ for each $g \mid T$. Suppose there exists some $h \in G$ with $g h \mid T$ such that $\left|I_{g} \cap I_{h}\right| \geq 2$. Then Proposition 4.4(3) shows that $\Omega\left(G_{0}, g h\right) \not \subset \mathcal{G}_{1}(G)$ and we set $R=g h$. Thus we assume that if $g h \mid T$, then $\left|I_{g} \cap I_{h}\right| \leq 1$. Note that this is only possible if $r \geq 3$. Thus in case $r \leq 2$ our arguments already yield the existence of a subsequence $R \mid S$ with the claimed properties. Moreover, it follows that $T$ is squarefree, i.e., $\mathrm{v}_{g}(T) \leq 1$ for each $g \in G$.

STEP 4. We assert that there exists a subsequence $T^{\prime}=\left(\prod_{j=1}^{s} g_{j}^{\prime}\right) \mid T$ with $r \geq s \geq 3$ such that the sets $I_{j}^{\prime}=I_{g_{j}^{\prime}}$ satisfy the conditions of Proposition $4.4(4)$, i.e., for every $J \subset[1, s]$ with $|J| \geq 2$,

$$
\left|\bigcap_{j \in J} I_{j}^{\prime}\right|= \begin{cases}1 & \text { if } J=\left\{j, j^{\prime}\right\} \text { and } j-j^{\prime} \equiv \pm 1 \bmod s \\ 0 & \text { otherwise }\end{cases}
$$

Then $\Omega\left(G_{0}, T^{\prime}\right) \not \subset \mathcal{G}_{1}(G)$ and we set $R=T^{\prime}$.
We prove by induction on $r$ that a sequence $T$ with $|T|=r \geq 3$, where $\left|I_{g} \cap I_{h}\right| \leq 1$ and $\left|I_{g}\right| \geq 2$ for each $g h \mid T$, has a subsequence with the claimed properties. For ease of notation we will write $I_{j}$ instead of $I_{g_{j}}$.

Let $r=3$. Since $\left|I_{g} \cap I_{h}\right| \leq 1$ and $\left|I_{g}\right| \geq 2$ for $g h \mid T$, it follows that $\left|I_{g}\right|<3$ for each $g \mid T$ and $|T|=3$. Thus $T=g_{1} g_{2} g_{3}$ and $\left\{I_{1}, I_{2}, I_{3}\right\}=$ $\{\{1,2\},\{2,3\},\{1,3\}\}$. We set $T^{\prime}=T$ and number the elements in a suitable way.

Let $r>3$. For $j \in[1, r]$ let $T_{j} \mid T$ denote the subsequence of the elements $g \mid T$ with $j \in I_{g}$.

CASE 1: There exists some $j \in[1, r]$ such that $\left|T_{j}\right| \leq 1$. Without restriction let $j=r$. We apply the induction hypothesis to the sequence $T_{r}^{-1} T$ to deduce that there exists a subsequence $T^{\prime} \mid T_{r}^{-1} T$ with $\left|T^{\prime}\right| \leq r-1$ and the claimed properties.

CASE 2: $\left|T_{j}\right| \geq 2$ for each $j \in[1, r]$. We define the sequence $T^{\prime} \mid T$ by a recursive construction. Let $j_{0}=1, g_{1} \mid T_{j_{0}}$ and $j_{1} \in I_{1} \backslash\left\{j_{0}\right\}$. Let $i \geq 1$ and suppose $g_{m}$ and $j_{m}$ are constructed for $m \in[1, i]$. Then let $g_{i+1} \mid g_{i}^{-1} T_{j_{i}}$. If $I_{i+1} \cap \bigcup_{m=1}^{i} I_{m}=\left\{j_{i}\right\}$, then let $j_{i+1} \in I_{i} \backslash\left\{j_{i}\right\}$ and proceed with the construction.

If $\left|I_{i+1} \cap \bigcup_{m=1}^{i} I_{m}\right| \geq 2$, then let $m^{\prime}=\max \left\{m \in[0, i-1] \mid I_{m} \cap I_{i+1} \neq \emptyset\right\}$ and set $T^{\prime}=\prod_{j=m^{\prime}}^{i+1} g_{j}$. Note that $\left|\bigcup_{m=1}^{i} I_{m}\right| \geq i+1$. Thus if $i=r-1$, then we would have $\bigcup_{m=1}^{i} I_{m}=[1, r]$ and the construction would stop. Changing the index set by setting $g_{j}^{\prime}=g_{j+1-m^{\prime}}$, we obtain the sequence $T^{\prime}$ as claimed. This proves the statement for $k=1$.

Let $k \geq 2$ and suppose the statement holds for $k^{\prime}<k$. Let $S=\prod_{i=1}^{l} g_{i} \in$ $\mathcal{F}\left(G \backslash G_{0}\right)$ with $l \geq r p-1+(k-1) \max \{p, r\}$. Clearly, $l \geq r p-1$ and there
exists a subsequence $R \mid S$ such that $\Omega\left(G_{0}, R\right) \not \subset \mathcal{G}_{1}(G)$ and $|R| \leq \max \{p, r\}$. Since $\left|R^{-1} S\right| \geq r p-1+(k-2) \max \{p, r\}$, we deduce by induction hypothesis that $\Omega\left(G_{0}, R^{-1} S\right) \not \subset \mathcal{G}_{k-1}(G)$. This implies $\Omega\left(G_{0}, S\right) \not \subset \mathcal{G}_{k}(G)$.

Parts of the proof, in particular in Step 4, just depend on the system of sets (the hypergraph) $\left([1, r],\left(I_{g}\right)_{g \mid T}\right)$. Thus the proof could be shortened by using results on hypergraphs (cf. for example [5, in particular 2.1]). As mentioned in the Introduction we can solve the problem [22, P 1247] in the following special case.

Corollary 4.6. Let $p \geq 3$ and $G$ be an elementary $p$-group with $\mathrm{r}(G)$ $=2 r$. If $p \geq r$, then $\left(\psi_{k}(G)\right)_{k=1}^{\infty}$ is an arithmetic progression.
4.2. Groups with odd rank. In this section we investigate elementary $p$-groups with odd rank. The results we obtain are much weaker than the ones for groups with even rank, and we mainly establish lower bounds. We start with the investigation of groups with rank 1 and consider the more general situation of cyclic groups with prime power order.

The following characterization result on half-factorial sets in cyclic groups with prime power order was proved by various authors in slightly different formulations (cf. [7, Corollary 5.4] for a proof and detailed references).

Proposition 4.7. Let $G$ be cyclic with $|G|=p^{m}$ for some $p \in \mathbb{P}$ and $m \in \mathbb{N}$. Then $\mu(G)=m+1$, and $G_{0} \subset G$ is half-factorial with $\left|G_{0}\right|=\mu(G)$ if and only if $G_{0}=\left\{p^{i} g \mid i \in[0, m]\right\}$ for some $g \in G$ with $\operatorname{ord}(g)=p^{m}$.

We apply this characterization to obtain a technical result and first lower bounds.

Proposition 4.8. Let $G$ be cyclic with $|G|=p^{m}$ for some $p \in \mathbb{P}$ and $m \in \mathbb{N}$.
(1) Let $G_{0}=\left\{p^{i} e \mid i \in[0, m]\right\}$ with $e \in G$ and $\operatorname{ord}(e)=p^{m}$. Further let $g=a e \in G \backslash G_{0}$ with $a \in\left[2, p^{m}-1\right]$ such that $p \nmid a$. If $l \in \mathbb{N}_{0}$ with $l(a-1)<p^{m}$, then $\emptyset \neq \Omega\left(G_{0}, g^{l}\right) \subset \mathcal{G}_{1}(G)$. In particular, $\mathrm{L}(C)=\left\{\mathrm{k}(C)+l(a-1) / p^{m}\right\}$ for each $C \in \Omega\left(G_{0}, g^{l}\right)$.
(2) If $p \geq 3$, then $\psi_{1}(G) \geq p^{m}-1$.
(3) If $p=2$, then $\psi_{1}(G) \geq 2^{m-1}-1$.

Proof. (1) By Proposition 4.7 we know that $G_{0}$ is half-factorial and $\left|G_{0}\right|=\mu(G)$. Clearly, $\left\langle G_{0}\right\rangle=G$ and thus $\Omega\left(G_{0}, S\right) \neq \emptyset$ for every $S \in$ $\mathcal{F}\left(G \backslash G_{0}\right)$. Let $l \in \mathbb{N}_{0}$ be such that $l(a-1)<p^{m}$.

We first prove the following statement on cross numbers of certain atoms: If $A \in \mathcal{A}\left(G_{0} \cup\{g\}\right)$ with $\mathrm{v}_{g}(A)=v \leq l$, then $\mathrm{k}(A)=1-v(a-1) / p^{m}$. Let $A \in$ $\mathcal{A}\left(G_{0} \cup\{g\}\right)$ with $\vee_{g}(A)=v \leq l$. By [12, Lemma 2] we know that $\mathrm{k}\left(A^{\prime}\right) \leq 1$ for every $A^{\prime} \in \mathcal{A}(G)$. Let $B=g^{-v} e^{a v} A \in \mathcal{B}\left(G_{0}\right)$. Since $G_{0}$ is half-factorial,
we know $\mathrm{k}(B) \in \mathbb{N}$. Thus we have $1 \leq \mathrm{k}(B)=\mathrm{k}(A)+v(a-1) / p^{m}<2$ and consequently $\mathrm{k}(B)=1$ and $\mathrm{k}(A)=1-v(a-1) / p^{m}$.

Let $C \in \Omega\left(G_{0}, g^{l}\right)$ and $C=\prod_{i=1}^{n} U_{i}$ be a factorization with $U_{i} \in \mathcal{A}(G)$ and $\mathrm{v}_{g}\left(U_{i}\right)=v_{i}$ for each $i \in[1, n]$. Then

$$
\mathrm{k}(C)=\sum_{i=1}^{n} \mathrm{k}\left(U_{i}\right)=\sum_{i=1}^{n}\left(1-\frac{v_{i}(a-1)}{p^{m}}\right)=n-\mathrm{v}_{g}(C) \frac{a-1}{p^{m}}
$$

and $n=\mathrm{k}(C)+l(a-1) / p^{m}$ is determined by $C$. Consequently, $\mathrm{L}(C)=$ $\left\{\mathrm{k}(C)+l(a-1) / p^{m}\right\}$ and $\Omega\left(G_{0}, g^{l}\right) \subset \mathcal{G}_{1}(G)$.
(2) and (3). Note that if $p=2$, then $m \geq 2$, since by our general assumption $|G| \geq 3$. Let $G_{0} \subset G$ be half-factorial with $\left|G_{0}\right|=\mu(G)$. By Proposition 4.7 we know that $G_{0}$ satisfies the conditions of (1). For $p \geq 3$, we set $g=2 e$. Since $\left(p^{m}-1\right)(2-1)<p^{m}$, Proposition 4.8 shows that $\psi_{1}(G) \geq p^{m}-1$. For $p=2$, we set $g=3 e$. Since $\left(2^{m-1}-1\right)(3-1)<2^{m}$, we obtain $\psi_{1}(G) \geq 2^{m-1}-1$.

This lower bound is in general not sharp as the following result shows. However, for $p^{m}=4$ and $p^{m}=3$ equality holds. As already mentioned in the Introduction, this was initially obtained in [21, 22]. For $p^{m}=3$ we state this result (cf. [21, Corollary 2]) in the first part of the following lemma.

Proposition 4.9. Let $|G| \in \mathbb{P}$ and $k \in \mathbb{N}$.
(1) If $|G|=3$, then $\psi_{k}(G)=3 k-1$.
(2) If $|G| \geq 5$, then $\psi_{k}(G) \geq p k-1+(p-1) / 2$.

Proof. Let $G_{0} \subset G$ be half-factorial with $\left|G_{0}\right|=\mu(G)=2$. Then $G_{0}=$ $\{0, e\}$ with some $e \in G \backslash\{0\}$.
(1) Let $|G|=3$. We note that $\mathcal{A}(G)=\left\{0, e(2 e), e^{3},(2 e)^{3}\right\}$. Since $(2 e)^{3} e^{3}$ $=((2 e) e)^{3}$, we have $\Omega\left(G_{0},(2 e)^{3}\right) \not \subset \mathcal{G}_{1}(G)$ and consequently $\psi_{1}(G)<3$. Using Lemma 3.2 we obtain

$$
\psi_{k}(G) \leq(k-1)\left(\psi_{1}(G)+1\right)+\psi_{1}(G) \leq 3 k-1
$$

It remains to show that $\Omega\left(G_{0},(2 e)^{3 k-1}\right) \subset \mathcal{G}_{k}(G)$. Let $B \in \mathcal{B}(G)$ and

$$
B=\prod_{i=1}^{n^{\prime}} V_{i}=((2 e) e)^{m} \prod_{i=1}^{n} U_{i}
$$

where $U_{i} \neq(2 e) e$ for each $i \in[1, n]$. Since $\mathrm{k}(B)=m \frac{2}{3}+n$, we see that $n$ is determined by $m$ and $\mathrm{k}(B)$. Moreover, $m \equiv \mathrm{v}_{2 e}(B) \bmod 3$. Thus for $C \in \Omega\left(G_{0},(2 e)^{3 k-1}\right)$ there are at most $k$ possible values for $m$. This implies $|\mathrm{L}(C)| \leq k$.
(2) Let $|G| \geq 5$ and $S=(2 e)^{k p-1}(-2 e)^{(p-1) / 2}$. We show $\emptyset \neq \Omega\left(G_{0}, S\right)$ $\subset \mathcal{G}_{k}(G)$.

Note that if $A \in \mathcal{A}(\{0, e, 2 e,-2 e\})$ with $0<\mathrm{v}_{-2 e}(A) \leq(p-1) / 2$, then $A=(-2 e) 2 e$ or $A=(-2 e) e^{2}$. Let $C \in \Omega\left(G_{0}, S\right)$ and

$$
C=\prod_{i=1}^{n^{\prime}} V_{i}=\left((2 e)^{p}\right)^{m} \prod_{i=1}^{n} U_{i}
$$

with $U_{i} \neq(2 e)^{p}$ for each $i \in[1, r]$ be a factorization into atoms. Clearly, $m \in[0, k-1]$. We assert that $n$ is determined by $m$ and $C$. Since there are at most $k$ possible values for $m$, this implies that $|\mathrm{L}(C)| \leq k$.

Since $\mathrm{v}_{-2 e}(C)=(p-1) / 2$, there exists some subset $I \subset[1, n]$ with $|I|=(p-1) / 2$ such that $U_{i} \in\left\{(-2 e) 2 e,(-2 e) e^{2}\right\}$ for each $i \in I$. Let $l=\left|\left\{i \in I \mid U_{i}=(-2 e) e^{2}\right\}\right| \in[0,(p-1) / 2]$. Then we have

$$
C^{\prime}=\left((2 e)^{p}\right)^{m} \prod_{i \in[1, n] \backslash I} U_{i} \in \Omega\left(G_{0},(2 e)^{k p-p+(p-1) / 2+l}\right)
$$

We have $\mathrm{k}\left(U_{i}\right)=1-\mathrm{v}_{2 e}\left(U_{i}\right) / p$ for each $i \in[1, n] \backslash I$ (cf. proof of Proposition 4.8). Thus

$$
\begin{aligned}
\mathrm{k}\left(C^{\prime}\right) & =m+\sum_{i \in[1, n] \backslash I}\left(1-\frac{\mathrm{v}_{2 e}\left(U_{i}\right)}{p}\right)=m+n-\frac{p-1}{2}-\frac{\mathrm{v}_{2 e}\left(C^{\prime}\right)}{p} \\
& =m+n-\frac{p-1}{2}-(k-1)-\frac{p-1+2 l}{2 p}
\end{aligned}
$$

Since $\mathrm{k}\left(C^{\prime}\right)=\mathrm{k}(C)-\sum_{i \in I} \mathrm{k}\left(U_{i}\right)=\mathrm{k}(C)-\frac{p-1}{2} \frac{2}{p}-l \frac{1}{p}$, we obtain

$$
\mathrm{k}(C)=m+n-\frac{p-1}{2}+k-1+\frac{3(p-1)}{2 p}
$$

Thus $n$ just depends on $m$ and $\mathrm{k}(C)$.
Next we combine the results on cyclic groups with the ones on elementary $p$-groups with even rank to establish lower bounds for elementary $p$-groups with odd rank. Again we neglect $p=2$, since we will treat elementary 2 -groups in the following section.

In [9, Theorem 8] it was proved that if $G$ is an elementary $p$-group with odd $\operatorname{rank} \mathrm{r}(G)=2 r+1$, then $2+r p \leq \mu(G) \leq 1+r p+\lfloor p / 2\rfloor$. For $p \in\{2,3\}$ this implies $\mu(G)=2+r p$, and for $p \in\{5,7\}$ it was proved in [19, Theorem 3.2]. Note that if $G=G^{\prime} \oplus G^{\prime \prime}$ and $\mu(G)=2+r p$, then $\mu(G)=\mu\left(G^{\prime}\right)+\mu\left(G^{\prime \prime}\right)-1$.

Corollary 4.10. Let $r \in \mathbb{N}_{0}, k \in \mathbb{N}$ and $G$ be an elementary p-group with $\mathrm{r}(G)=2 r+1$.
(1) If $p=3$, then $\psi_{k}(G) \geq 3(k+r)-1$.
(2) If $p \geq 5$ and $\mu(G)=2+r p$, then $\psi_{k}(G) \geq p(k+r)-1+(p-1) / 2$.

Proof. Let $p \in \mathbb{P}$. For $r=0$ the result is just Lemma 4.9. Let $r \geq 1$ and $G=G^{\prime} \oplus G^{\prime \prime}$ with $\mathrm{r}\left(G^{\prime}\right)=2 r$ and $\mathrm{r}\left(G^{\prime \prime}\right)=1$. Since $\mu(G)=\mu\left(G^{\prime}\right)+$ $\mu\left(G^{\prime \prime}\right)-1$, we can apply Lemma 3.1(4). We apply the lower bounds obtained in Lemma 4.3 for $\psi_{k}\left(G^{\prime}\right)$, and in Lemma 4.9 for $\psi_{1}\left(G^{\prime \prime}\right)$, and the statement follows.

Remark 4.11. Similarly to [18, Theorem $7.1(6)$ ] we can prove that for every $p \in \mathbb{P}$ there exists some $r_{p} \in \mathbb{N}$ such that $\psi_{k}(G) \geq(k-1+$ $\left.\left(r-r_{p}\right) / 2\right) p-1$ for every elementary $p$-group $G$ with $\mathrm{r}(G) \geq r_{p}$.
5. $\psi_{k}(G)$ for elementary 2-groups. Until the end of this section let $G$ denote an elementary 2-group with $\mathrm{r}(G)=r \geq 2$. In [14, Problem II] it was proved that $\mu(G)=r+1$ and that $G_{0} \subset G$ is half-factorial if and only if $G_{0} \backslash\{0\}$ is independent. Thus again all half-factorial subsets with maximal cardinality are equal up to automorphisms. Throughout the whole section let $\left\{e_{1}, \ldots, e_{r}\right\} \subset G$ be a basis and $G_{0}=\left\{0, e_{1}, \ldots, e_{r}\right\}$ be a half-factorial set with $\left|G_{0}\right|=\mu(G)$. Further let $\pi_{i}$ denote the projection on $\left\langle e_{i}\right\rangle$ for each $i \in[1, r]$.

We start with the following short lemma that provides a first lower bound.

Lemma 5.1. Let $k \in \mathbb{N}$. Then $\psi_{k}(G) \geq 2(k-1)+r-1$.
Proof. If $r$ is even, then this is just Lemma 4.3. Suppose $r$ is odd and let $G=G^{\prime} \oplus G^{\prime \prime}$ with $\left|G^{\prime \prime}\right|=2$. Then $\psi_{k}(G) \geq \psi_{k}\left(G^{\prime}\right)+1 \geq 2(k-1)+r-2+1$ by Lemmas 3.1(4) and 4.3.

As mentioned in the Introduction, we will apply notions and results of extremal graph theory to determine $\psi_{k}(G)$ (in terms of constants introduced there). We will show (cf. Theorem 5.7) that to determine $\psi_{k}(G)$ is equivalent to determining the maximal number of edges in a graph on $r$ vertices not containing $k$ edge disjoint cycles. We use the convention that a graph may have multiple edges but no loops. Apart from that our terminology concerning (multi)graphs will follow [1].

We define for each $S \in \mathcal{F}\left(G \backslash G_{0}\right)$ an associated graph with vertex set $[1, r]$. In general this graph is not uniquely determined. Conversely, we define for each graph with vertex set [1,r] its (uniquely determined) associated sequence $S \in \mathcal{F}\left(G \backslash G_{0}\right)$.

Definition 5.2. Let $l \in \mathbb{N}$.
(1) Let $S=\prod_{i=1}^{l} g_{i} \in \mathcal{F}\left(G \backslash G_{0}\right)$. For $i \in[1, l]$ let $I_{i}=\{j \in[1, r] \mid$ $\left.\pi_{j}\left(g_{i}\right)=e_{j}\right\}$ and let $E_{i} \subset I_{i}$ be some subset with $\left|E_{i}\right|=2$. The graph $\left([1, r],\left(E_{i}\right)_{i \in[1, l]}\right)$ is called an associated graph of $S$.
(2) Let $\left([1, r],\left(E_{i}\right)_{i \in[1, l]}\right)$ be a graph. For $i \in[1, l]$ let $g_{i}=\sum_{j \in E_{i}} e_{j}$. Then $S=\prod_{i=1}^{l} g_{i} \in \mathcal{F}\left(G \backslash G_{0}\right)$ is called the associated sequence of $\left([1, r],\left(E_{i}\right)_{i \in[1, l]}\right)$.
Example 5.3. Let $S=\left(e_{1}+e_{2}\right)^{2(k-1)} \prod_{i=1}^{r-1}\left(e_{i}+e_{i+1}\right)$. The sequence $S$ is an example of a sequence with $|S|=2(k-1)+r-1$ and $\Omega\left(G_{0}, S\right) \subset \mathcal{G}_{k}(G)$. Its associated graph (in this special case it is uniquely determined) is a path where one edge is a multiple edge with multiplicity $2 k-1$. Note that this graph contains exactly $k-1$ edge disjoint cycles.

In the following two lemmata we prove that the number of edge disjoint cycles in an associated graph of $S$ and sets of lengths of $B \in \Omega\left(G_{0}, S\right)$ are closely related.

Lemma 5.4. Let $k \in \mathbb{N}, S=\prod_{i=1}^{l} g_{i} \in \mathcal{F}\left(G \backslash G_{0}\right)$ and $\left([1, r],\left(E_{i}\right)_{i \in[1, l]}\right)$ be an associated graph that contains $k$ edge disjoint cycles. Then $\Omega\left(G_{0}, S\right) \not \subset$ $\mathcal{G}_{k}(G)$.

Proof. Let $I_{i}=\left\{j \in[1, r] \mid \pi_{j}\left(g_{i}\right)=e_{j}\right\}$ for each $i \in[1, l]$. Then $A_{i}=$ $g_{i} \prod_{j \in I_{i}} e_{j} \in \mathcal{A}(G)$ and $B=\prod_{i=1}^{l} A_{i} \in \Omega\left(G_{0}, S\right)$. It suffices to show that $B \notin \mathcal{G}_{k}(G)$.

We proceed by induction on $k$. Let $k=1$ and let $C \subset[1, l]$ be such that $\left(E_{i}\right)_{i \in C}$ are the edges of a cycle and $V_{C} \subset[1, r]$ is the set of vertices occurring in this cycle. We consider $B^{\prime}=\prod_{i \in C} A_{i}$ and obtain $B^{\prime}=\left(\prod_{i \in V_{C}} e_{i}^{2}\right) B^{\prime \prime}$ with $B^{\prime \prime} \in \mathcal{B}(G) \backslash\{1\}$. Since $|C|=\left|V_{C}\right|$, we have $\mathrm{L}\left(B^{\prime}\right) \geq 2$ and $B \notin \mathcal{G}_{1}(G)$.

Let $k \geq 2$ and suppose the statement holds for $1 \leq k^{\prime}<k$. Again let $C \subset$ $[1, l]$ be such that $\left(E_{i}\right)_{i \in C}$ are the edges of a cycle and $\left([1, r],\left(E_{i}\right)_{i \in[1, l] \backslash C}\right)$ has $k-1$ edge disjoint cycles. We have $B=B^{\prime} B^{\prime \prime}$ with $B^{\prime}=\prod_{i \in C} A_{i}$ and $B^{\prime \prime}=\prod_{i \in[1, l] \backslash C} A_{i}$. By induction hypothesis we get $B^{\prime} \notin \mathcal{G}_{1}(G)$ and $B^{\prime \prime} \notin \mathcal{G}_{k-1}(G)$. Thus we obtain $B \notin \mathcal{G}_{k}(G)$.

Lemma 5.5. Let $\left([1, r],\left(E_{i}\right)_{i \in[1, l]}\right)$ be a graph that does not contain $k$ edge disjoint cycles, and $S$ its associated sequence. Then $\Omega\left(G_{0}, S\right) \subset \mathcal{G}_{k}(G)$.

Proof. By definition we have $g=e_{i}+e_{j}$ for distinct $i, j \in[1, r]$ for every $g \mid S$, i.e., $S \in \mathcal{F}\left(\left(G_{0}+G_{0}\right) \backslash G_{0}\right)$. Thus $\Omega\left(G_{0}, S\right) \subset \mathcal{B}\left(G_{0}+G_{0}\right)$. We start with an investigation of $\mathcal{A}\left(G_{0}+G_{0}\right)$. Let $A \in \mathcal{A}\left(G_{0}+G_{0}\right) \backslash\{0\}$.
(1) Suppose $\mathrm{v}_{e_{i}}(A)=0$ for every $i \in[1, r]$, i.e., $A \mid S$. We assert that the corresponding edges are the edges of a cycle. Let $g_{1}=e_{j_{0}}+e_{j_{1}} \mid A$. There exists some $g_{2} \mid g_{1}^{-1} A$ such that $g_{2}=e_{j_{1}}+e_{j_{2}}$. If $j_{2} \in\left\{j_{0}, j_{1}\right\}$, equivalently $j_{2}=j_{0}$, then $\sigma\left(g_{1} g_{2}\right)=0$ and $A=g_{1} g_{2}$. Otherwise we proceed with a recursive construction. Let $i \geq 2$ and $g_{i}=e_{j_{i-1}}+e_{j_{i}}$ be such that $j_{i} \notin$ $\left\{j_{0}, \ldots, j_{i-1}\right\}$. Then there exists some $g_{i+1} \mid\left(\prod_{j=1}^{i} g_{j}\right)^{-1} A$ such that $g_{i+1}=$ $e_{j_{i}}+e_{j_{i+1}}$. If $j_{i+1} \in\left\{j_{0}, \ldots, j_{i}\right\}$, say $j_{i+1}=j_{m}$, then $\sigma\left(\prod_{j=m+1}^{i+1} g_{j}\right)=0$.

Thus it follows that $m=0$ and $A=\prod_{j=1}^{i+1} g_{j}$. For $i=r-1$ we would have $\left\{j_{0}, \ldots, j_{i}\right\}=[1, r]$ and thus $j_{i+1} \in\left\{j_{0}, \ldots, j_{i}\right\}$. Thus $A=\prod_{j=1}^{s} g_{j}$ for some $s \in[2, r]$ and the associated edges are the edges of a cycle with vertices $\left\{j_{0}, \ldots, j_{s-1}\right\}$.
(2) Suppose $e_{j_{0}} \mid A$ for some $j_{0} \in[1, r]$. We set $g_{0}=e_{j_{0}}$. If $e_{j_{0}} \mid\left(g_{0}^{-1} A\right)$, we set $g_{1}=e_{j_{0}}$ and it follows that $A=g_{0} g_{1}=e_{j_{0}}^{2}$. Otherwise there exists some $j_{1} \notin\left\{j_{0}\right\}$ such that $g_{1}=\left(e_{j_{0}}+e_{j_{1}}\right) \mid\left(g_{0}^{-1} A\right)$ and we proceed with a recursive construction. Let $i \geq 1$ and $g_{i}=e_{j_{i-1}}+e_{j_{i}}$ be such that $j_{i} \notin$ $\left\{j_{0}, \ldots, j_{i-1}\right\}$. If $e_{j_{i}} \mid\left(\prod_{j=0}^{i} g_{j}\right)^{-1} A$, we set $g_{i+1}=e_{j_{i}}$ and it follows that $A=\prod_{j=0}^{i+1} g_{j}$. Otherwise there exists some $g_{i+1} \mid\left(\prod_{j=0}^{i} g_{j}\right)^{-1} A$ such that $g_{i+1}=e_{j_{i}}+e_{j_{i+1}}$. It follows that $j_{i+1} \notin\left\{j_{0}, \ldots, j_{i}\right\}$, since otherwise $A$ would have a proper zero-sum subsequence (cf. (1) for a detailed argument). Similarly to (1), if $i=r-1$ we have $\left\{j_{0}, \ldots, j_{i}\right\}=[1, r]$ and thus necessarily $e_{j_{i}} \mid\left(\prod_{j=0}^{i} g_{j}\right)^{-1} A$. Thus $A=\prod_{j=0}^{s} g_{j}$ for some $s \in[2, r]$. In particular, $A=$ $\prod_{j=0}^{s} g_{j}=e_{j_{0}} e_{j_{s-1}} \prod_{j=1}^{s-1} g_{j}$ and the edges associated to $g_{j}$ for $j \in[1, s-1]$ are the edges of a path from $j_{0}$ to $j_{s-1}$.

We summarize these results. Let $A \in \mathcal{A}\left(G_{0}+G_{0}\right)$. If $A \notin \mathcal{A}\left(\left(G_{0}+G_{0}\right) \backslash\right.$ $\left.G_{0}\right)$, then $\mathrm{k}(A)=1+\frac{1}{2} \sum_{g \in G \backslash G_{0}} \mathrm{v}_{g}(A)$. If $A \in \mathcal{A}\left(\left(G_{0}+G_{0}\right) \backslash G_{0}\right)$, then $\mathrm{k}(A)=\frac{1}{2} \sum_{g \in G \backslash G_{0}} \mathrm{v}_{g}(A)$ and the associated edges are the edges of a cycle in the associated graph.

Let $B \in \Omega\left(G_{0}, S\right)$ and $B=\prod_{i=1}^{n} U_{i}$ be a factorization of $B$ into atoms. Further let $m=\left|\left\{i \mid U_{i} \in \mathcal{A}\left(\left(G_{0}+G_{0}\right) \backslash G_{0}\right)\right\}\right|$. Recall that each of these $m$ atoms is associated to a cycle and thus $m \in[0, k-1]$. We have

$$
\mathrm{k}(B)=\sum_{i=1}^{n} \mathrm{k}\left(U_{i}\right)=n-m+\frac{1}{2} \sum_{i=1}^{n} \sum_{g \in G \backslash G_{0}} \mathrm{v}_{g}\left(U_{i}\right)=n-m+\frac{|S|}{2} .
$$

This implies $\mathrm{L}(B) \subset \mathrm{k}(B)-|S| / 2+[0, k-1]$ and thus $\Omega\left(G_{0}, S\right) \subset \mathcal{G}_{k}(G)$.
The following constants are investigated in extremal graph theory (cf. [1, Chapter III.3] for detailed references and proofs of the results we mention).

Definition 5.6. Let $k, n \in \mathbb{N}$.
(1) $\mathrm{p}(k)$ denotes the smallest integer $l$ with the property: every graph with $v$ vertices, for some $v \in \mathbb{N}$, and $v+l$ edges contains at least $k$ edge disjoint cycles.
(2) $\mathrm{p}(k, n)$ denotes the smallest integer $l$ with the property: every graph with $n$ vertices and $n+l$ edges contains at least $k$ edge disjoint cycles.

By definition $\mathrm{p}(k, n) \leq \mathrm{p}(k)$ and $\mathrm{p}(k, n) \leq \mathrm{p}(k+1, n)$. Moreover, there exists some $n_{k} \in \mathbb{N}$ such that $\mathrm{p}(k, n)=\mathrm{p}(k)$ if $n \geq n_{k}$. It is well known that there exists a graph not containing a cycle with $n$ vertices and $n-1$ edges, i.e., $\mathrm{p}(k, n) \geq 0$.

For $\mathrm{p}(\cdot)$ the following is known:

- $\mathrm{p}(k)+4 \leq \mathrm{p}(k+1)$.
- $\mathrm{p}(1)=0, \mathrm{p}(2)=4, \mathrm{p}(3)=10$, and $\mathrm{p}(4)=18$.
- $\frac{1}{2} k \log _{2} k<\mathrm{p}(k) \leq 2 k\left(\log _{2} k+\log _{2} \log _{2} k+2\right)$ if $k \geq 2$.

The following theorem summarizes the results of Lemmas 5.4 and 5.5.
Theorem 5.7. Let $k \in \mathbb{N}$ and $G$ be an elementary 2-group with rank $r$. Then $\psi_{k}(G)=r-1+\mathrm{p}(k, r)$. In particular,
(1) $\psi_{1}(G)=r-1$.
(2) $2(k-1)+r-1 \leq \psi_{k}(G) \leq r-1+\mathrm{p}(k)$.
(3) $\psi_{k}(G)=r-1+\mathrm{p}(k)$ if $r \geq r_{k}$ for some $r_{k} \in \mathbb{N}$.

Proof. Let $S \in \mathcal{F}\left(G \backslash G_{0}\right)$ with $|S| \geq r+\mathrm{p}(k, r)$. By definition every associated graph of $S$ contains $k$ edge disjoint cycles. By Lemma 5.4 this implies $\psi_{k}(G)<r+\mathrm{p}(k, r)$.

Conversely, by definition of $\mathbf{p}(k, r)$ there exists a graph with $r$ vertices and $r-1+\mathrm{p}(k, r)$ edges that does not contain $k$ edge disjoint vertices. Let $S$ denote the associated sequence. By Lemma 5.5 we have $\Omega\left(G_{0}, S\right) \subset \mathcal{G}_{k}(G)$ and $\psi_{k}(G) \geq|S|=r-1+\mathrm{p}(k, r)$.

The additional statements follow, since $\mathrm{p}(1)=0, \mathrm{p}(k, r) \geq 2(k-1)$ (also cf. Lemma 5.1), $\mathrm{p}(k, r) \leq \mathrm{p}(k)$, and $\mathrm{p}(k, r)=\mathrm{p}(k)$ for sufficiently large $r$. -

Theorem 5.7 and $\mathrm{p}(k)+4 \leq \mathrm{p}(k+1)$ imply that the lower bound in Lemma 5.1 is in general not sharp. For example, the graph $K^{3,3}$, the complete bipartite graph, is a graph with 6 vertices and $6+\mathrm{p}(2)-1=9$ edges not containing 2 edge disjoint cycles. Thus $\psi_{2}(G)=r+3>2+r-1$ for $r \geq 6$. However, if $r \in[2,3]$, then $\mathrm{p}(k, r)=2(k-1)$ and thus $\psi_{k}(G)=2(k-1)+r-1$, i.e., equality holds in Lemma 5.1 (for $r=2$ cf. [22, Section 3]).

Moreover, the results on $\mathrm{p}(\cdot)$ show that $\left(\psi_{k}(G)\right)_{k=1}^{\infty}$ is not an arithmetic progression if $G$ is an elementary 2-group with sufficiently large rank. In order to be able to give an example of a number field with class group having this property, we point out that $\mathrm{p}(1,4)=0, \mathrm{p}(2,4)=3$, where the complete graph $K^{4}$ serves as example, and $\mathrm{p}(3,4)=5$. Thus if $G$ is an elementary 2 -group with rank 4 , then $\left(\psi_{k}(G)\right)_{k=1}^{\infty}$ is not an arithmetic progression. Note that if $\psi_{k}(G)>\psi_{k-1}(G)$, then it follows that the maximum in the definition of $\psi_{k}(G)$ is realized by a block with $|\mathrm{L}(B)|=k$ (also cf. [8, Lemma 3]) and therefore in this case $\psi_{k}(G)=B(k, G)$ and $\psi_{k}(G)=\bar{\psi}_{k}(G)$ with $\bar{\psi}_{k}(G)$ as in [8]. Using the KANT database ([4]) we find that the class group of $\mathbb{Q}(\sqrt{-1365})$ is isomorphic to $C_{2}^{4}$.

Remark 5.8. For elementary $p$-groups with even rank $2 r$, where $p \geq 3$, one can apply similar ideas to those for $p=2$ and obtain an alternative and thus improved upper bound for $\psi_{k}(G)$. In particular, these bounds yield
$\psi_{k}(G) \leq(k-1+r) p-1+\mathrm{p}(k)$, which implies that for each $k \in \mathbb{N}$ the gap between the lower and improved upper bounds does not exceed $\mathrm{p}(k)$, whence is independent of $G$. However, for arbitrary $p$ it seems that we cannot improve the lower bound in the way it was done for $p=2$.

Addendum. Recently, A. Plagne and the author proved that $\mu\left(C_{p}^{2 r+1}\right)$ $=2+r p$ for $p \in \mathbb{P}$ and $r \in \mathbb{N}_{0}$. Thus, the condition in Corollary $4.10(2)$ is in fact always fulfilled.
