Abstract

Given a group $X$ we study the algebraic structure of the compact right-topological semigroup $\lambda(X)$ consisting of all maximal linked systems on $X$. This semigroup contains the semigroup $\beta(X)$ of ultrafilters as a closed subsemigroup. We construct a faithful representation of the semigroup $\lambda(X)$ in the semigroup $\mathcal{P}(X)^{\mathcal{P}(X)}$ of all self-maps of the power-set $\mathcal{P}(X)$ and show that the image of $\lambda(X)$ in $\mathcal{P}(X)^{\mathcal{P}(X)}$ coincides with the semigroup $\text{End}_\lambda(\mathcal{P}(X))$ of all functions $f : \mathcal{P}(X) \to \mathcal{P}(X)$ that are equivariant, monotone and symmetric in the sense that $f(X \setminus A) = X \setminus f(A)$ for all $A \subset X$. Using this representation we describe the minimal ideal $K(\lambda(X))$ and minimal left ideals of the superextension $\lambda(X)$ of a twinic group $X$. A group $X$ is called twinic if it admits a left-invariant ideal $\mathcal{I} \subset \mathcal{P}(X)$ such that $xA = \mathcal{I} yA$ for all subsets $A \subset X$ and points $x, y \in X$ with $xA \subset \mathcal{I} X \setminus A \subset \mathcal{I} yA$. The class of twinic groups includes all amenable groups and all groups with periodic commutators but does not include the free group $F_2$ with two generators.

We prove that for any twinic group $X$, there is a cardinal $m$ such that all minimal left ideals of $\lambda(X)$ are algebraically isomorphic to

$$2^m \times \prod_{1 \leq k \leq \infty} C_{2^k}^{q(X,C_{2^k})} \times \prod_{3 \leq k \leq \infty} Q_{2^k}^{q(X,C_{2^k})}$$

for some cardinals $q(X,C_{2^k})$ and $q(X,Q_{2^k})$, $k \in \mathbb{N} \cup \{\infty\}$. Here $C_{2^k}$ is the cyclic group of order $2^k$, $C_{2^\infty}$ is the quasicyclic 2-group and $Q_{2^k}$, $k \in \mathbb{N} \cup \{\infty\}$, are the groups of generalized quaternions. If the group $X$ is abelian, then $q(X,Q_{2^k}) = 0$ for all $k$ and $q(X,C_{2^k})$ is the number of subgroups $H \subset X$ with quotient $X/H$ isomorphic to $C_{2^k}$.

If $X$ is an abelian group (admitting no epimorphism onto $C_{2^\infty}$), then each minimal left ideal of the superextension $\lambda(X)$ is algebraically (and topologically) isomorphic to the product $\prod_{1 \leq k \leq \infty} (C_{2^k} \times 2^{2^{k-1} - 1} \text{ for } k = \infty)$ where the cube $2^{2^{k-1} - 1}$ (equal to $2^\omega$ if $k = \infty$) is endowed with the left zero multiplication. For an abelian group $X$, all minimal left ideals of $\lambda(X)$ are metrizable if and only if $X$ has finite ranks $r_0(X)$ and $r_2(X)$ and admits no homomorphism onto the group $C_{2^\infty} \oplus C_{2^\infty}$.

Applying this result to the group $\mathbb{Z}$ of integers, we prove that each minimal left ideal of $\lambda(\mathbb{Z})$ is topologically isomorphic to $2^\omega \times \prod_{k = 1}^{\infty} C_{2^k}$. Consequently, all subgroups in the minimal ideal $K(\lambda(\mathbb{Z}))$ of $\lambda(\mathbb{Z})$ are profinite abelian groups. On the other hand, the superextension $\lambda(\mathbb{Z})$ contains an isomorphic topological copy of each second countable profinite topological semigroup. This results contrasts with the famous Zelenyuk Theorem saying that the semigroup $\beta(\mathbb{Z})$ contains no finite subgroups. At the end of the paper we describe the structure of minimal left ideals of finite groups $X$ of order $|X| \leq 15$.

2010 Mathematics Subject Classification: 20M30, 20M12, 22A15, 22A25, 54D35.

Key words and phrases: compact right-topological semigroup, superextension of a group, semi-group of maximal linked systems, faithful representation, minimal ideal, minimal left ideal, minimal idempotent, wreath product, twinic group, twin set.

1. Introduction

After discovering a topological proof of Hindman’s theorem [10] (see [12, p. 102], [11]), topological methods have become a standard tool in the modern combinatorics of numbers (see [12], [18]). The crucial point is that any semigroup operation defined on a discrete space $X$ can be extended to a right-topological semigroup operation on $\beta(X)$, the Stone–Čech compactification of $X$. The extension of the operation from $X$ to $\beta(X)$ can be defined by the simple formula

$$A \circ B = \{A \subset X : \{x \in X : x^{-1}A \in B\} \in A\}. \quad (1.1)$$

The Stone–Čech compactification $\beta(X)$ of $X$ is a subspace of the double power-set $P^2(X) = P(P(X))$, which can be identified with the Cantor discontinuum $\{0, 1\}^{P(X)}$ and endowed with the compact Hausdorff topology of the Tikhonov product. It turns out that the formula (1.1) applied to arbitrary families $A, B \in P^2(X)$ of subsets of a group $X$ still defines a binary operation $\circ : P^2(X) \times P^2(X) \to P^2(X)$ that turns the double power-set $P^2(X)$ into a compact Hausdorff right-topological semigroup that contains $\beta(X)$ as a closed subsemigroup.

The semigroup $\beta(X)$ lies in a slightly larger subsemigroup $\lambda(X) \subset P^2(X)$ consisting of all maximal linked systems on $X$. We recall that a family $\mathcal{L}$ of subsets of $X$ is

- **linked** if any sets $A, B \in \mathcal{L}$ have non-empty intersection $A \cap B \neq \emptyset$;
- **maximal linked** if $\mathcal{L}$ coincides with each linked system $\mathcal{L}'$ on $X$ that contains $\mathcal{L}$.

The space $\lambda(X)$ is well-known in General and Categorial Topology as the superextension of $X$ (see [15], [22]).

The thorough study of algebraic properties of the superextensions of groups was started in [4] and continued in [2] and [3]. In particular, in [3] we proved that the minimal left ideals of the superextension $\lambda(\mathbb{Z})$ are metrizable topological semigroups. In this paper we shall extend this result to the superextensions $\lambda(X)$ of all finitely-generated abelian groups $X$.

The results obtained in this paper completely reveal the topological and algebraic structure of the minimal ideal and minimal left ideals of the superextension $\lambda(X)$ of a twinic group $X$. A group $X$ is defined to be **twinic** if it admits a left-invariant ideal $\mathcal{I}$ of subsets of $X$ such that for any subset $A \subset X$ with $xA \subset \mathcal{I} X \setminus A \subset \mathcal{I} yA$ for some $x, y \in X$ we have $xA =_\mathcal{I} yA$. Here the symbol $A \subset_\mathcal{I} B$ means that $A \setminus B \in \mathcal{I}$ and $A =_\mathcal{I} B$ means that $A \subset_\mathcal{I} B$ and $B \subset_\mathcal{I} A$. In Section 6 we shall prove that the class of twinic groups contains all amenable groups and all groups with periodic commutators (in particular, all torsion groups), but does not contain the free group $F_2$ with two generators.
We need to recall the notation for some standard 2-groups. We denote by $Q_8$ the group of quaternions. It is a multiplicative subgroup $\{1, i, j, k, -1, -i, -j, -k\}$ of the real algebra $\mathbb{H}$ of quaternions (which contains the field $\mathbb{C}$ of complex numbers as a subalgebra).

For every $k \in \omega$ let $C_{2^k} = \{z \in \mathbb{C} : z^{2^k} = 1\}$ be the cyclic group of order $2^k$. The multiplicative subgroup $Q_{2^k} \subset \mathbb{H}$ generated by the union $C_{2^{k-1}} \cup Q_8$ is called the group of generalized quaternions. The union $C_{2^\omega} = \bigcup_{k=1}^{\infty} C_{2^k}$ is called the quasicyclic 2-group and the union $Q_{2^\omega} = \bigcup_{k=3}^{\infty} Q_{2^k}$ is called the infinite group of generalized quaternions. By Theorem 8.1, a group $G$ is isomorphic to $C_{2^n}$ or $Q_{2^n}$ for some $n \in \mathbb{N} \cup \{\infty\}$ if and only if $G$ is a 2-group with a unique 2-element subgroup.

The following theorem describing the structure of minimal left ideals of the superextensions of twinic groups can be derived from Theorem 1.1 and Proposition 1.1:

**Theorem 1.1.** For each twinic group $X$ there are cardinals $q(X, C_{2^k}), q(X, Q_{2^k}), k \in \mathbb{N} \cup \{\infty\}$, such that

1. each minimal left ideal of $\lambda(X)$ is algebraically isomorphic to
   
   $Z \times \prod_{1 \leq k \leq \infty} C_{2^k}^{q(X, C_{2^k})} \times \prod_{3 \leq k \leq \infty} Q_{2^k}^{q(X, Q_{2^k})}$

   for some semigroup $Z$ of left zeros;

2. each maximal subgroup of the minimal ideal of $\lambda(X)$ is algebraically isomorphic to

   $\prod_{1 \leq k \leq \infty} C_{2^k}^{q(X, C_{2^k})} \times \prod_{3 \leq k \leq \infty} Q_{2^k}^{q(X, Q_{2^k})}$.

3. If $q(X, C_{2^\omega}) = q(X, Q_{2^\omega}) = 0$, then each maximal subgroup of the minimal ideal of $
\lambda(X)$ is topologically isomorphic to the compact topological group

   $\prod_{1 \leq k < \infty} C_{2^k}^{q(X, C_{2^k})} \times \prod_{3 \leq k < \infty} Q_{2^k}^{q(X, Q_{2^k})}$.

If the group $X$ is abelian, then

4. $q(X, Q_{2^k}) = 0$ for every $k \in \mathbb{N} \cup \{\infty\}$ while $q(X, C_{2^k})$ is equal to the number of

   subgroups $H \subset X$ such that the quotient group $X/H$ is isomorphic to $C_{2^k}$;

5. for every $k \in \mathbb{N}$,

   $q(X, C_{2^k}) = \frac{|\text{hom}(X, C_{2^k})| - |\text{hom}(X, C_{2^{k-1}})|}{2^{k-1}},$

   where $\text{hom}(X, C_{2^k})$ is the group of homomorphisms from $X$ into $C_{2^k}$.

### 2. Right-topological semigroups

In this section we recall some information from [12] related to right-topological semigroups. By definition, a right-topological semigroup is a topological space $S$ endowed with a semigroup operation $*: S \times S \to S$ such that for every $a \in S$ the right shift $r_a : S \to S$, $r_a : x \mapsto x * a$, is continuous. If the semigroup operation $*: S \times S \to S$ is (separately) continuous, then $(S, *)$ is a (semi-)topological semigroup. A typical example of a right-topological semigroup is the semigroup $X^X$ of all self-maps of a topological space $X$. 

---

endowed with the Tikhonov product topology and the binary operation of composition of functions.

From now on, \( S \) is a compact Hausdorff right-topological semigroup. We shall recall some known information concerning ideals in \( S \) (see \[12\]).

A non-empty subset \( I \) of \( S \) is called a left (resp. right) ideal if \( SI \subset I \) (resp. \( IS \subset I \)). If \( I \) is both a left and right ideal in \( S \), then \( I \) is called an ideal in \( S \). Such an ideal is called principal. An ideal \( I \subset S \) is called \textit{minimal} if any ideal of \( S \) that lies in \( I \) coincides with \( I \). By analogy we define minimal left and right ideals of \( S \). It is easy to see that each minimal left (resp. right) ideal \( I \) is principal. Moreover, \( I = Sx \) (resp. \( I = xS \)) for each \( x \in I \). This simple observation implies that each minimal left ideal in \( S \), being principal, is closed in \( S \). By \[12, 2.6\], each left ideal in \( S \) contains a minimal left ideal. The union \( K(S) \) of all minimal left ideals of \( S \) coincides with the minimal ideal of \( S \), \[12, 2.8\].

All minimal left ideals of \( S \) are mutually homeomorphic and all maximal groups of the minimal ideal \( K(S) \) are algebraically isomorphic. Moreover, if two maximal groups lie in the same minimal right ideal, then they are topologically isomorphic.

We shall need the following known fact (see \[12, Theorem 2.11(c)\]).

**Proposition 2.1.** For any two minimal left ideals \( A,B \) of a compact right-topological semigroup \( S \) and any point \( b \in B \) the right shift \( r_b : A \to B, r_b : x \mapsto xb \), is a homeomorphism.

This proposition implies the following corollary (see \[3, Lemma 1.1\]).

**Corollary 2.2.** If a homomorphism \( h : S \to S' \) between two compact right-topological semigroups is injective on some minimal left ideal of \( S \), then \( h \) is injective on each minimal left ideal of \( S \).

An element \( z \) of a semigroup \( S \) is called a right zero (resp. a left zero) in \( S \) if \( xz = z \) (resp. \( zx = z \)) for all \( x \in S \). It is clear that \( z \in S \) is a right (left) zero in \( S \) if and only if the singleton \( \{ z \} \) is a left (right) ideal in \( S \).

An element \( e \in S \) is called an \textit{idempotent} if \( ee = e \). By Ellis’s Theorem \[12, 2.5\], the set \( E(S) \) of idempotents of any compact right-topological semigroup is not empty. For every idempotent \( e \) the set
\[
H_e = \{ x \in S : \exists x^{-1} \in S \ (xx^{-1}x = x, \ x^{-1}xx^{-1} = x^{-1}, \ xx^{-1} = e = x^{-1}x) \}
\]
is the largest subgroup of \( S \) containing \( e \).

By \[12, 1.48\], for an idempotent \( e \in E(S) \) the following conditions are equivalent:
- \( e \in K(S) \);
- \( K(S) = SeS \);
- \( Se \) is a minimal left ideal in \( S \);
- \( eS \) is a minimal right ideal in \( S \);
- \( eSe \) is a subgroup of \( S \).

An idempotent \( e \) satisfying the above equivalent conditions will be called a \textit{minimal idempotent} in \( S \). By \[12, 1.64\], for any minimal idempotent \( e \in S \) the set \( E(Se) = E(S) \cap Se \).
of idempotents of the minimal left ideal $Se$ is a semigroup of left zeros, which means that $xy = x$ for all $x, y \in E(Se)$. By the Rees–Suschkewitsch Structure Theorem (see [12, 1.64]) the map

$$\varphi : E(Se) \times H_e \to Se, \quad \varphi : (x, y) \mapsto xy,$$

is an algebraic isomorphism of the corresponding semigroups. If the minimal left ideal $Se$ is a topological semigroup, then $\varphi$ is a topological isomorphism.

Now we see that all the information on the algebraic (and sometimes topological) structure of the minimal left ideal $Se$ is encoded in the properties of the left zero semigroup $E(Se)$ and the maximal group $H_e$.

3. Acts and their endomorphism monoids

In this section we survey the information on acts that will be widely used in this paper to describe the algebraic structure of minimal left ideals of the superextensions of groups.

Following the terminology of [13] by an act we understand a set $X$ endowed with a left action $\cdot : H \times X \to X$ of a group $H$ called the structure group of the act. The action should satisfy two axioms: $1x = x$ and $g(hx) = (gh)x$ for all $x \in X$ and $g, h \in H$. Acts with the structure group $H$ will be called $H$-acts or $H$-spaces.

An act $X$ is called free if the stabilizer $\text{Fix}(x) = \{h \in H : hx = x\}$ of each point $x \in X$ is trivial. For a point $x \in X$ we denote by $[x] = \{hx : h \in H\}$ its orbit and by $[X] = \{[x] : x \in X\}$ the orbit space of the act $X$. More generally, for each subset $A \subset X$ we put $[A] = \{[a] : a \in A\}$.

A function $f : X \to Y$ between two $H$-acts is called equivariant if $f(hx) = hf(x)$ for all $x \in X$ and $h \in H$. A function $f : X \to Y$ is called an isomorphism of the $H$-acts $X$ and $Y$ if it is bijective and equivariant. An equivariant self-map $f : X \to X$ is called an endomorphism of the $H$-act $X$. If $f$ is bijective, then $f$ is an automorphism of $X$.

The set $\text{End}(X)$ of endomorphisms of an $H$-act $X$, endowed with the operation of composition of functions, is a monoid called the endomorphism monoid of $X$.

Each free $H$-act $X$ is isomorphic to the product $H \times [X]$ endowed with the action $h \cdot (x, y) = (hx, y)$. For such an act the semigroup $\text{End}(X)$ is isomorphic to the wreath product $H \wr [X]^{[X]}$ of the group $H$ and the semigroup $[X]^{[X]}$ of all self-maps of the orbit space $[X]$.

The wreath product $H \wr A^A$ of a group $H$ and the semigroup $A^A$ of self-maps of a set $A$ is defined as the semidirect product $H^A \rtimes A^A$ of the $A$-th power of $H$ with $A^A$, endowed with the semigroup operation $(h, f) \ast (h', f') = (h''(\alpha), f'')$ where $f'' = f \circ f'$ and $h''(\alpha) = h(f'(\alpha)) \cdot h'(\alpha)$ for $\alpha \in A$. For any subsemigroup $S \subset A^A$ the subset $H \wr S = \{(h, f) \in H^A \rtimes A^A : f \in S\}$ is called the wreath product of $H$ and $S$. If both $H$ and $S$ are groups, then their wreath product $H \wr S$ is a group.

Observe that the maximal subgroup of $A^A$ containing the identity self-map of $A$ coincides with the group $S_A$ of all bijective functions $f : A \to A$.

**Theorem 3.1.** Let $H$ be a group and $X$ be a free $H$-act. Then

1. the semigroup $\text{End}(X)$ is isomorphic to the wreath product $H \wr [X]^{[X]}$;
(2) the minimal ideal $K(\text{End}(X))$ of $\text{End}(X)$ coincides with the set $\{f \in \text{End}(X) : \forall x \in f(X) f(X) \subset [x]\}$;
(3) each minimal left ideal of $\text{End}(X)$ is isomorphic to $H \times [X]$ where $[X]$ is endowed with the left zero multiplication;
(4) for each idempotent $f \in \text{End}(X)$ the maximal subgroup $H_f \subset \text{End}(X)$ is isomorphic to $H \wr S_{[f(X)]}$;
(5) for each minimal idempotent $f \in K(\text{End}(X))$ the maximal group $H_f = f \cdot \text{End}(X) \cdot f$ is isomorphic to $H$.

**Proof.** 1. Let $\pi : X \rightarrow [X]$, $\pi : x \mapsto [x]$, denote the orbit map and $s : [X] \rightarrow X$ be a section of $\pi$, which means that $\pi \circ s([x]) = [x]$ for all $[x] \in [X]$.

Observe that each equivariant map $f : X \rightarrow X$ induces a well-defined map $[f] : [X] \rightarrow [X]$, $[f] : [x] \mapsto [f(x)]$, of the orbit spaces. Since the action of $H$ on $X$ is free, for every orbit $[x] \in [X]$ we can find a unique point $f_H([x]) \in H$ such that $f \circ s([x]) = (f_H([x]))^{-1} \cdot s([f(x)])$.

We claim that the map

$$
\Psi : \text{End}(X) \rightarrow H \wr [X]^{[X]}, \quad \Psi : f \mapsto (f_H, [f]),
$$

is a semigroup isomorphism.

First we check that the map $\Psi$ is a homomorphism. Pick any two equivariant functions $f, g \in \text{End}(X)$ and consider their images $\Psi(f) = (f_H, [f])$ and $\Psi(g) = (g_H, [g])$ in $H \wr [X]^{[X]}$. Consider also the composition $f \circ g$ and its image $\Psi(f \circ g) = ((f \circ g)_H, [f \circ g])$.

We claim that

$$
((f \circ g)_H, [f \circ g]) = (f_H, [f]) \ast (g_H, [g]) = ((f_H \circ [g]) \cdot g_H, [f] \circ [g]).
$$

The equality $[f \circ g] = [f] \circ [g]$ is clear. To prove that $(f \circ g)_H = (f_H \circ [g]) \cdot g_H$, take any orbit $[x] \in [X]$. It follows from the definition of $(f \circ g)_H([x])$ that

$$
((f \circ g)_H([x]))^{-1} \cdot s([f \circ g(x)]) = (f \circ g) \circ s([x]) = f(g \circ s([x]))
= f((g_H([x]))^{-1} \cdot s([g(x)])) = (g_H([x]))^{-1} \cdot f \circ s([g(x)])
= (g_H([x]))^{-1} \cdot (f_H([g(x)]))^{-1} \cdot s([f \circ g(x)])
= (f_H \circ [g])([x]) \cdot g_H([x])^{-1} \cdot s([f \circ g(x)]),
$$

which implies the desired equality $(f \circ g)_H = (f_H \circ [g]) \cdot g_H$.

Next, we show that the homomorphism $\Psi$ is injective. Given two equivariant functions $f, g \in \text{End}(X)$ with $(f_H, [f]) = \Psi(f) = \Psi(g) = (g_H, [g])$, we need to show that $f = g$.

Observe that for every orbit $[x] \in [X]$ we get

$$
f(s([x])) = (f_H([x]))^{-1} \cdot s \circ f([x]) = (g_H([x]))^{-1} \cdot s \circ g([x]) = g(s([x])).
$$

Now for each $x \in X$ we can find a unique $h \in H$ with $x = h \cdot s([x])$ and apply the equivariance of the functions $f, g$ to conclude that

$$
f(x) = f(h \cdot s([x])) = h \cdot f(s([x])) = h \cdot g(s([x])) = g(h \cdot s([x])) = g(x).
$$

Finally, we show that $\Psi$ is surjective. Given any pair $(h, g) \in H \wr [X] = H[X] \times [X]^{[X]}$, we define an equivariant function $f \in \text{End}(X)$ with $(h, g) = (f_H, [f])$ as follows. Given
any \( x \in X \) find a unique \( y \in H \) with \( x = y \cdot s([x]) \) and let

\[
f(x) = y \cdot h([x])^{-1} \cdot s(g([x])).
\]

This formula determines a well-defined equivariant function \( f : X \to X \) with \( \Psi(f) = (h, g) \). Therefore, \( \Psi : \text{End}(X) \to H \wr [X]^{[X]} \) is a semigroup isomorphism.

2. Observe that the set \( \mathcal{I} = \{ f \in \text{End}(X) : \{ [f(x)] : x \in X \} \text{ is a singleton} \} \) is a (non-empty) ideal in \( \text{End}(X) \). To show that \( \mathcal{I} \) is the minimal ideal of the semigroup \( \text{End}(X) \), we need to check that any function \( f \in \mathcal{I} \) is a singleton by the second item. By the preceding item the maximal group \( \mathcal{J} \) is isomorphic to \( H \wr [X]^{[X]} \). Observe that the set \( \{ [f(x)] : x \in X \} \) such that \( [f(z)] = [x] \) for all \( z \in X \). Since the restriction \( g[x] : [x] \to [g(x)] \) is bijective and equivariant, so is its inverse \( (g[x])^{-1} : [g(x)] \to [x] \). Extend this equivariant map to any equivariant map \( h : X \to X \). Then

\[
f = h \circ g \circ f \in \text{End}(X) \circ g \circ \text{End}(X) \subset \mathcal{J}.
\]

3. Take any idempotent \( f \in K(\text{End}(X)) \) and consider the minimal left ideal \( \text{End}(X) \cdot f \). Fix any point \( z \in f(X) \) and observe that \( f([x]) = [z] \) for all \( x \in X \) according to the preceding item. It follows that the set \( Z = f^{-1}(z) \) meets each orbit \([x], x \in X \), in a single point. So, we can define a unique section \( s : [X] \to Z \subset X \) of the orbit map \( X \to [X] \) such that \( f \circ s([X]) = \{z\} \).

To each equivariant map \( g \in \text{End}(X) \) assign a unique element \( g_H \in H \) such that \( g(x) = g_H^{-1} \cdot s([g(x)]) \). It is easy to check that the map

\[
\Phi : \text{End}(X) \cdot f \to H \times [X], \quad \Phi : g \mapsto (g_H, [g]([x])),
\]

is a semigroup homomorphism where the orbit space \([X] \) is endowed with the left zero multiplication.

4. Take any idempotent \( f \in \text{End}(X) \) and consider the surjective semigroup homomorphism \( \text{pr} : \text{End}(X) \to [X]^{[X]} \), \( \text{pr} : g \mapsto [g] \). It follows that \([f] \) is an idempotent of the semigroup \([X]^{[X]} \) and the image \( \text{pr}(H_f) \) of the maximal group \( H_f \) is a subroup of \([X]^{[X]} \). It is easy to see that the maximal subgroup \( H_{[f]} \) of the idempotent \([f] \) in \([X]^{[X]} \) coincides with \( S_{[f(X)]} \cdot [f] \). The preimage \( \text{pr}^{-1}(H_{[f]}) \) of the maximal subgroup \( H_{[f]} = S_{[f(X)]} \cdot f \) is isomorphic to the wreath product \( H \wr H_{[f]} \) and hence is a group. Now the maximality of \( H_f \) guarantees that \( H_f = \text{pr}^{-1}(H_{[f]}) \) and hence \( H_f \) is isomorphic to \( H \wr S_{[f(X)]} \).

5. If \( f \in K(\text{End}(X)) \) is a minimal idempotent, then the set \( \{ [f(x)] : x \in X \} \) is a singleton by the second item. By the preceding item the maximal group \( H_f \) is isomorphic to \( H \wr S_{[f(X)]} \), which is isomorphic to the group \( H \) since \([f(X)] \) is a singleton.

For each group \( X \) the power-set \( P(X) \) will be considered as an \( X \)-act endowed with the left action

\[
\cdot : X \times P(X) \to P(X), \quad (x, A) \mapsto xA = \{xa : a \in A\},
\]

of the group \( X \). This \( X \)-act \( P(X) \) and its endomorphism monoid \( \text{End}(P(X)) \) will play a crucial role in our considerations.
4. The function representation of the semigroup $P^2(X)$

In this section given a group $X$ we construct a topological isomorphism

$$\Phi : P^2(X) \rightarrow \text{End}(P(X))$$

called the *function representation* of the semigroup $P^2(X)$ in the endomorphism monoid of the $X$-act $P(X)$. We recall that the double power-set $P^2(X) = P(P(X))$ of the group $X$ is endowed with the binary operation

$$A \circ B = \{ A \subset X : \{ x \in X : x^{-1}A \in B \} \in A \}.$$  

The isomorphism $\Phi$ assigns to each family $A$ of subsets of $X$ the function

$$\Phi_A : P(X) \rightarrow P(X), \quad \Phi_A : A \mapsto \{ x \in X : x^{-1}A \in A \},$$

called the *function representation* of $A$.

In the following theorem by $e$ we denote the neutral element of the group $X$.

**Theorem 4.1.** For any group $X$ the map $\Phi : P^2(X) \rightarrow \text{End}(P(X))$ is a topological isomorphism with inverse $\Phi^{-1} : \varphi \mapsto \{ A \subset X : e \in \varphi(A) \}$.

**Proof.** First observe that for any family $A \in P^2(X)$ the function $\Phi_A$ is equivariant, because

$$\Phi_A(xA) = \{ y \in X : y^{-1}xA \in A \} = \{ xz \in X : z^{-1}A \in A \} = x\Phi_A(A)$$

for any $x \in X$ and $A \subset X$. Thus the map $\Phi : P^2(X) \rightarrow \text{End}(P(X))$ is well-defined.

To prove that $\Phi$ is a semigroup homomorphism, take two families $\mathcal{X}, \mathcal{Y} \in P^2(X)$ and let $\mathcal{Z} = \mathcal{X} \circ \mathcal{Y}$. We need to check that $\Phi_{\mathcal{Z}}(A) = \Phi_{\mathcal{X}} \circ \Phi_{\mathcal{Y}}(A)$ for every $A \subset X$. Observe that

$$\Phi_{\mathcal{Z}}(A) = \{ z \in X : z^{-1}A \in \mathcal{Z} \} = \{ z \in X : \{ x \in X : x^{-1}z^{-1}A \in \mathcal{Y} \} \in \mathcal{X} \}$$

$$= \{ z \in X : \Phi_{\mathcal{Y}}(z^{-1}A) \in \mathcal{X} \} = \{ z \in X : z^{-1}\Phi_{\mathcal{Y}}(A) \in \mathcal{X} \}$$

$$= \Phi_{\mathcal{X}}(\Phi_{\mathcal{Y}}(A)) = \Phi_{\mathcal{X}} \circ \Phi_{\mathcal{Y}}(A).$$

To see that the map $\Phi$ is injective, take any two distinct families $\mathcal{A}, \mathcal{B} \in P^2(X)$. Without loss of generality, $\mathcal{A} \setminus \mathcal{B}$ contains some set $A \subset X$. It follows that $e \in \Phi_{\mathcal{A}}(A)$ but $e \notin \Phi_{\mathcal{B}}(A)$ and hence $\Phi_{\mathcal{A}} \neq \Phi_{\mathcal{B}}$.

To see that the map $\Phi$ is surjective, take any equivariant function $\varphi : P(X) \rightarrow P(X)$ and consider the family $\mathcal{A} = \{ A \subset X : e \in \varphi(A) \}$. It follows that for every $A \in P(X)$,

$$\Phi_{\mathcal{A}}(A) = \{ x \in X : x^{-1}A \in \mathcal{A} \} = \{ x \in X : e \in \varphi(x^{-1}A) \}$$

$$= \{ x \in X : e \in x^{-1}\varphi(A) \} = \{ x \in X : x \in \varphi(A) \} = \varphi(A).$$

To prove that $\Phi : P^2(X) \rightarrow \text{End}(P(X)) \subset P(X)^{P(X)}$ is continuous we first define a convenient subbase of the topology on the spaces $P(X)$ and $P(X)^{P(X)}$. The product topology of $P(X)$ is generated by the subbase consisting of the sets

$$x^+ = \{ A \subset X : x \in A \} \quad \text{and} \quad x^- = \{ A \subset X : x \notin A \}$$

where $x \in X$. On the other hand, the product topology on $P(X)^{P(X)}$ is generated by the subbase consisting of the sets

$$\langle x, A \rangle^+ = \{ f \in P(X)^{P(X)} : x \in f(A) \} \quad \text{and} \quad \langle x, A \rangle^- = \{ f \in P(X)^{P(X)} : x \notin f(A) \}$$

where $A \in P(X)$ and $x \in X$. 
Now observe that the preimage
\[ \Phi^{-1}(\langle x, A \rangle^+) = \{ A \in P^2(X) : x \in \Phi(A) \} = \{ A \in P^2(X) : x^{-1} A \in A \} \]
is open in \( P^2(X) \). The same is true for the preimage
\[ \Phi^{-1}(\langle x, A \rangle^-) = \{ A \in P^2(X) : x \notin \Phi(A) \} = \{ A \in P^2(X) : x^{-1} A \notin A \}. \]

Since the spaces \( P^2(X) \cong \{0,1\}^P(X) \) and \( \text{End}(P(X)) \subset P(X)^P(X) \) are compact and Hausdorff, the continuity of the map \( \Phi \) implies the continuity of its inverse \( \Phi^{-1} \). Consequently, \( \Phi : P^2(X) \to \text{End}(P(X)) \) is a topological isomorphism of compact right-topological semigroups. ■

**Remark 4.2.** The function representations \( \Phi_A \) of some families \( A \subset P(X) \) have transparent topological interpretations. For example, if \( A \) is the filter of neighborhoods of the identity element \( e \) of a left-topological group \( X \) and \( A^\perp = \{ B \subset X : \forall A \in A \ (B \cap A \neq \emptyset) \} \), then for any subset \( B \subset X \) the set \( \Phi_A(B) \) coincides with the interior of the set \( B \) while \( \Phi_{A^\perp}(B) \) with the closure of \( B \) in \( X \!

Theorem 4.1 has a strategical importance because it allows us to translate (usually difficult) problems concerning the structure of the semigroup \( P^2(X) \) to (usually more tractable) problems about the endomorphism monoid \( \text{End}(P(X)) \). In particular, Theorem 4.1 implies “for free” that the binary operation on \( P^2(X) \) is associative and right-topological and hence \( P^2(X) \) is indeed a compact right-topological semigroup. Now let us investigate the interplay between the properties of a family \( A \in P^2(X) \) and those of its function representation \( \Phi_A \).

Let us define a family \( A \subset P(X) \) to be

- **monotone** if for any subsets \( A \subset B \subset X \) the inclusion \( A \subset A \) implies \( B \subset B \);
- **left-invariant** if for any \( A \subset A \) and \( x \subset X \) we get \( xA \subset A \).

Correspondingly, a function \( \varphi : P(X) \to P(X) \) is called

- **monotone** if \( \varphi(A) \subset \varphi(B) \) for any subsets \( A \subset B \subset X \);
- **symmetric** if \( \varphi(X \setminus A) = X \setminus \varphi(A) \) for every \( A \subset X \).

**Proposition 4.3.** For an equivariant function \( \varphi \in \text{End}(P(X)) \) the family \( \Phi^{-1}(\varphi) = \{ A \subset X : e \in \varphi(A) \} \) is

1. monotone if and only if \( \varphi \) is monotone;
2. left-invariant if and only if \( \varphi(P(X)) \subset \{ \emptyset, X \} \);
3. maximal linked if and only if \( \varphi \) is monotone and symmetric.

**Proof.** Let \( A = \Phi^{-1}(\varphi) \).

1. If \( \varphi \) is monotone, then for any sets \( A \subset B \) with \( A \subset A \) we get \( e \in \varphi(A) \subset \varphi(B) \) and hence \( B \subset A \), which means that the family \( A \) is monotone.

Now assume conversely that the family \( A \) is monotone and take any sets \( A \subset B \subset X \). Note that for any \( x \subset X \) with \( xA \subset A \) we get \( xB \subset A \). Then
\[ \varphi(A) = \{ x \subset X : x^{-1} A \subset A \} \subset \{ x \subset X : x^{-1} B \subset A \} = \varphi(B), \]
witnessing that the function \( \varphi \) is monotone.
2. If the family $\mathcal{A}$ is left-invariant, then for each $A \in \mathcal{A}$ we get $\varphi(A) = \{ x \in X : x^{-1}A \in A \} = X$ and for each $A \notin \mathcal{A}$ we get $\varphi(A) = \{ x \in X : x^{-1}A \in A \} = \emptyset$.

Now assume conversely that $\varphi(P(X)) \subset \{ \emptyset, X \}$. Then for each $A \in \mathcal{A}$ we get $e \in \varphi(A) = X$ and then for each $x \in X$, the equivariance of $\varphi$ guarantees that $\varphi(xA) = x\varphi(A) = xX = X \ni e$ and thus $xA \in \mathcal{A}$, witnessing that the family $\mathcal{A}$ is invariant.

3. Assume that the family $\mathcal{A}$ is maximal linked. By the maximality, $\mathcal{A}$ is monotone. Consequently, its function representation $\varphi$ is monotone. The maximal linked property of $\mathcal{A}$ guarantees that for any subset $A \subset X$ we get $(A \in \mathcal{A}) \iff (X \setminus A \notin \mathcal{A})$. Then
\[
\varphi(X \setminus A) = \{ x \in X : x^{-1}(X \setminus A) \in A \} = \{ x \in X : X \setminus x^{-1}A \in A \}
\]
\[
= \{ x \in X : x^{-1}A \notin A \} = X \setminus \{ x \in X : x^{-1}A \in A \} = X \setminus \varphi(A),
\]
which means that the function $\varphi$ is symmetric.

Now assuming that the function $\varphi$ is monotone and symmetric, we shall show that the family $\mathcal{A} = \Phi^{-1}(\varphi)$ is maximal linked. The statement (1) guarantees that $\mathcal{A}$ is monotone. Assuming that $\mathcal{A}$ is not linked, we could find two disjoint sets $A, B \in \mathcal{A}$. Since $\mathcal{A}$ is monotone, we can assume that $B = X \setminus A$. Then $e \in \varphi(A) \cap \varphi(X \setminus A)$, which is impossible as $\varphi(X \setminus A) = X \setminus \varphi(A)$. Thus $\mathcal{A}$ is linked. To show that $\mathcal{A}$ is maximal linked, it suffices to check that for each subset $A \subset X$ either $A$ or $X \setminus A$ belongs to $\mathcal{A}$. Since $\varphi(X \setminus A) = X \setminus \varphi(A)$, either $\varphi(A)$ or $\varphi(X \setminus A)$ contains the neutral element $e$ of the group $X$. In the first case $A \in \mathcal{A}$ and in the second case $X \setminus A \notin \mathcal{A}$. ■

Let us recall that the aim of this paper is the description of the structure of minimal left ideals of the superextension $\lambda(X)$ of a group $X$. Instead of the semigroup $\lambda(X)$ it will be more convenient to consider its isomorphic copy
\[
\text{End}_\lambda(P(X)) = \Phi(\lambda(X)) \subset \text{End}(P(X))
\]
called the function representation of $\lambda(X)$.

Proposition 4.3 implies

**Corollary 4.4.** The function representation $\text{End}_\lambda(P(X))$ of $\lambda(X)$ consists of equivariant monotone symmetric functions $\varphi : P(X) \to P(X)$.

In order to describe the structure of minimal left ideals of the semigroup $\text{End}_\lambda(P(X))$ we shall look for a relatively small subfamily $F \subset P(X)$ such that the restriction operator
\[
R_F : \text{End}_\lambda(P(X)) \to P(X)^F, \quad R_F : \varphi \mapsto \varphi|_F,
\]
is injective on each minimal left ideal of the semigroup $\text{End}_\lambda(P(X))$.

Then the composition
\[
\Phi_F = R_F \circ \Phi : \lambda(X) \to P(X)^F
\]
will be injective on each minimal left ideal of the semigroup $\lambda(X)$. By Proposition 2.2 a homomorphism between semigroups is injective on each minimal left ideal if it is injective on some minimal left ideal. Such a special minimal left ideal of the semigroup $\lambda(X)$ will be found in the left ideal of the form $\lambda^T(X)$ for a suitable left-invariant ideal $T$ of subsets of the group $X$. 
A family $\mathcal{I}$ of subsets of $X$ is called an *ideal* on $X$ if

- $X \notin \mathcal{I}$;
- $A \cup B \in \mathcal{I}$ for any $A, B \in \mathcal{I}$;
- for any $A \in \mathcal{I}$ and $B \subset A$ we get $B \in \mathcal{I}$.

Such an ideal $\mathcal{I}$ is called *left-invariant* (resp. *right-invariant*) if $xA \in \mathcal{I}$ (resp. $Ax \in \mathcal{I}$) for all $A \in \mathcal{I}$ and $x \in X$. An ideal $\mathcal{I}$ will be called *invariant* if it is both left-invariant and right-invariant.

The smallest ideal on $X$ is the trivial ideal $\{\emptyset\}$ containing only the empty set. The smallest non-trivial left-invariant ideal on an infinite group $X$ is the ideal $[X]<\omega$ of finite subsets of $X$. This ideal is invariant. From now on we shall assume that $\mathcal{I}$ is a left-invariant ideal on a group $X$.

For subsets $A, B \subset X$ we write

- $A \subset_\mathcal{I} B$ if $A \setminus B \in \mathcal{I}$;
- $A =_\mathcal{I} B$ if $A \subset_\mathcal{I} B$ and $B \subset_\mathcal{I} A$.

The definition of the ideal $\mathcal{I}$ implies that $=_\mathcal{I}$ is an equivalence relation on $\mathcal{P}(X)$. For a subset $A \subset X$ its equivalence class $\tilde{A} = \{B \subset X : B =_\mathcal{I} A\}$ is called the $\mathcal{I}$-*saturation* of $A$.

A family $\mathcal{A}$ of subsets of $X$ is defined to be $\mathcal{I}$-*saturated* if $\tilde{A} \subset \mathcal{A}$ for any $A \in \mathcal{A}$. Let us observe that a monotone family $\mathcal{A} \subset \mathcal{P}(X)$ is $\mathcal{I}$-saturated if and only if for any $A \in \mathcal{A}$ and $B \in \mathcal{I}$ we get $A \setminus B \in \mathcal{A}$.

Correspondingly, a function $\varphi : \mathcal{P}(X) \to \mathcal{P}(X)$ is called $\mathcal{I}$-*saturated* if $\varphi(A) = \varphi(B)$ for any subsets $A =_\mathcal{I} B$ of $X$.

**Proposition 4.5.** A family $\mathcal{A} \subset \mathcal{P}(X)$ is $\mathcal{I}$-saturated if and only if its function representation $\Phi_\mathcal{A} : \mathcal{P}(X) \to \mathcal{P}(X)$ is $\mathcal{I}$-saturated.

*Proof.* Assume that $\mathcal{A}$ is $\mathcal{I}$-saturated and take two subsets $A =_\mathcal{I} B$ of $X$. We need to show that $\Phi_\mathcal{A}(A) = \Phi_\mathcal{A}(B)$. The left-invariance of the ideal $\mathcal{I}$ implies that for every $x \in X$ we get $xA =_\mathcal{I} xB$ and hence $(xA \in \mathcal{A}) \iff (xB \in \mathcal{A})$. Then

$$
\Phi_\mathcal{A}(A) = \{x \in X : x^{-1}A \in \mathcal{A}\} = \{x \in X : x^{-1}B \in \mathcal{A}\} = \Phi_\mathcal{A}(B).
$$

Now assume conversely that the function representation $\Phi_\mathcal{A}$ is $\mathcal{I}$-saturated and take any subsets $A =_\mathcal{I} B$ with $A \in \mathcal{A}$. Then $e \in \Phi_\mathcal{A}(A) = \Phi_\mathcal{A}(B)$, which implies that $B \in \mathcal{A}$. $\blacksquare$

For a left-invariant ideal $\mathcal{I}$ on a group $X$ let $\lambda^\mathcal{I}(X) \subset \lambda(X)$ be the subspace of $\mathcal{I}$-saturated maximal linked systems on $X$ and $\End^\mathcal{I}_\lambda(\mathcal{P}(X)) \subset \End_\lambda(\mathcal{P}(X))$ be the subspace consisting of $\mathcal{I}$-saturated monotone symmetric endomorphisms of the $\mathcal{X}$-$\mathcal{P}(X)$. It is clear that for any functions $f, g : \mathcal{P}(X) \to \mathcal{P}(X)$ the composition $f \circ g$ is $\mathcal{I}$-saturated provided so is the function $g$. This trivial remark and Lemma 4.7 below imply:

**Proposition 4.6.** For any ideal $\mathcal{I}$ the function representation $\Phi : \lambda^\mathcal{I}(X) \to \End^\mathcal{I}_\lambda(\mathcal{P}(X))$ is a topological isomorphism between the closed left ideals $\lambda^\mathcal{I}(X)$ and $\End^\mathcal{I}_\lambda(\mathcal{P}(X))$ of the semigroups $\lambda(X)$ and $\End_\lambda(\mathcal{P}(X))$, respectively.

The following lemma (combined with Zorn’s Lemma) implies that the sets $\lambda^\mathcal{I}(X)$ and $\End^\mathcal{I}_\lambda(\mathcal{P}(X))$ are not empty.
Lemma 4.7. Each maximal $\mathcal{I}$-saturated linked system $\mathcal{L}$ on $X$ is maximal linked.

Proof. We need to show that each set $A \subset X$ that meets all sets $L \in \mathcal{L}$ belongs to $\mathcal{L}$. We claim that $A \notin \mathcal{I}$. Otherwise, taking any subset $L \in \mathcal{L}$, we get $L \setminus A =_{\mathcal{I}} L$ and hence $L \setminus A$ belongs to $\mathcal{L}$, which is not possible as $L \setminus A$ misses the set $A$. Since $A \notin \mathcal{I}$, the $\mathcal{I}$-saturated family $\bar{\mathcal{I}}^X$ is linked.

We claim that the $\mathcal{I}$-saturated family $\bar{\mathcal{I}}^X \cup \mathcal{L}$ is linked. Assuming the opposite, we would find two disjoint sets $A' \in \bar{\mathcal{I}}^X$ and $L \in \mathcal{L}$. Then $L \cap A =_{\mathcal{I}} L \cap A' = \emptyset$ and hence the set $L \setminus A =_{\mathcal{I}} L$ belongs to $\mathcal{L}$, which is not possible as this set misses $A$.

Now we see that the family $\bar{\mathcal{I}}^X \cup \mathcal{L}$, being $\mathcal{I}$-saturated and linked, coincides with the maximal $\mathcal{I}$-saturated linked system $\mathcal{L}$. Then $A \in \bar{\mathcal{I}}^X \cup \mathcal{L} = \mathcal{L}$. ■

Given a subfamily $F \subset P(X)$ consider the restriction operator

$$R_F : P(X)^{P(X)} \rightarrow P(X)^F, \quad R_F : f \mapsto f|F,$$

and let $\text{End}_\lambda(F) = R_F(\text{End}_\lambda(P(X)))$ and $\text{End}_\lambda^I(F) = R_F(\text{End}_\lambda^I(P(X)))$ for a left-invariant ideal $\mathcal{I}$ on $X$. The space $\text{End}_\lambda(F)$ is compact and Hausdorff as a continuous image of a compact Hausdorff space.

A subfamily $F \subset P(X)$ is called $\lambda$-invariant if $\Phi_{\mathcal{L}}(F) \subset F$ for each maximal linked system $\mathcal{L} \in \lambda(X)$. By Corollary 4.4 $F$ is $\lambda$-invariant if and only if $f(F) \subset F$ for each equivariant monotone symmetric function $f : P(X) \rightarrow P(X)$.

If a family $F \subset P(X)$ is $\lambda$-invariant, then the space $\text{End}_\lambda(F) \subset F^F$ is a compact right-topological semigroup with respect to the operation of composition of functions and the restriction operator $R_F : \text{End}_\lambda(P(X)) \rightarrow \text{End}_\lambda(F)$ is a surjective continuous semigroup homomorphism. In this case the composition

$$\Phi_F = R_F \circ \Phi : \lambda(X) \rightarrow \text{End}_\lambda(F)$$

is also a surjective continuous semigroup homomorphism and $\text{End}_\lambda^I(F) = \Phi_F(\lambda^I(X))$ is a left ideal in the semigroup $\text{End}_\lambda(F)$.

In the following proposition we characterize functions that belong to the space $\text{End}_\lambda^I(F)$ for an $\mathcal{I}$-saturated left-invariant symmetric subfamily $F \subset P(X)$. A family $F \subset P(X)$ is called symmetric if for each set $A \in F$ the complement $X \setminus A$ is in $F$.

Theorem 4.8. For a left-invariant ideal $\mathcal{I}$ on a group $X$ and an $\mathcal{I}$-saturated symmetric left-invariant family $F \subset P(X)$, a function $\varphi : F \rightarrow P(X)$ belongs to $\text{End}_\lambda^I(F)$ if and only if $\varphi$ is equivariant, symmetric, monotone, and $\mathcal{I}$-saturated.

Proof. The “only if” part follows immediately from Corollary 4.4. To prove the “if” part, fix any equivariant monotone symmetric $\mathcal{I}$-saturated function $\varphi : F \rightarrow P(X)$ and consider the families

$$\mathcal{L}_\varphi = \{x^{-1} A : A \in F, x \in \varphi(A)\} \quad \text{and} \quad \bar{\mathcal{L}}_\varphi^I = \bigcup_{A \in \mathcal{L}} \bar{\mathcal{I}}^X.$$

We claim that the family $\bar{\mathcal{L}}_\varphi^I$ is linked. Assuming the converse, we could find two sets $A, B \in F$ and two points $x \in \varphi(A)$ and $y \in \varphi(B)$ such that $x^{-1} A \cap y^{-1} B \in \mathcal{I}$. Then $yx^{-1} A \subset X \setminus B$ and hence $yx^{-1} A \subset (X \setminus B) \cup C$ for some set $C \in \mathcal{I}$. Since $F$ is symmetric and $\mathcal{I}$-saturated, the set $(X \setminus B) \cup C =_{\mathcal{I}} X \setminus B$ belongs to the family $F$. Applying to the
Indeed, take any set which is maximal linked by Lemma 4.7 and thus the group \( x \). Then the equivariant monotone symmetric (more generally, twinic) group \( \lambda \).

In this section we start studying very interesting objects called twin sets. For an abelian \( P \) semigroups in Sections 5–15, after which we shall return to studying minimal (left) ideals of the ideal of the superextension \( \Lambda \).

The families of twin and pretwin subsets of \( \lambda \) will be denoted by \( \mathcal{T} \) and \( \mathfrak{pT} \), respectively.

**Definition 5.1.** A subset \( A \subset X \) is defined to be

- **twin** if \( xA = X \setminus A \) for some \( x \in X \);
- **pretwin** if \( xA \subset X \setminus A \subset yA \) for some points \( x, y \in X \).

The families of twin and pretwin subsets of \( X \) will be denoted by \( \mathcal{T} \) and \( \mathfrak{pT} \), respectively.

Observe that a set \( A \subset X \) is twin if and only if \( \text{Fix}^{-}(A) \) is not empty.

The notion of a twin set has an obvious “ideal” version. For a left-invariant ideal \( \mathcal{I} \) of subsets of a group \( X \), and a subset \( A \subset X \), consider the following subsets of \( X \):

- \( \mathcal{I}-\text{Fix}(A) = \{ x \in X : xA =_{\mathcal{I}} A \} \),
- \( \mathcal{I}-\text{Fix}^{-}(A) = \{ x \in X : xA =_{\mathcal{I}} X \setminus A \} \),
- \( \mathcal{I}-\text{Fix}^{\pm}(A) = \mathcal{I}-\text{Fix}(A) \cup \mathcal{I}-\text{Fix}^{-}(A) \).

5. Twin and \( \mathcal{I} \)-twin subsets of groups

In this section we start studying very interesting objects called twin sets. For an abelian (more generally, twinic) group \( X \) the twin subsets of \( X \) form a subfamily \( \mathcal{T} \subset \mathcal{P}(X) \) for which the function representation \( \Phi_{\mathcal{T}} : \lambda(X) \to \text{End}_{\lambda}(\mathcal{T}) \) is injective on each minimal left ideal of the superextension \( \lambda(X) \). The machinery related to twin sets will be developed in Sections 3–15 after which we shall return to studying minimal (left) ideals of the semigroups \( \lambda(X) \) and \( \text{End}(X) \).

For a subset \( A \) of a group \( X \) consider the following three subsets of \( X \):

- \( \text{Fix}(A) = \{ x \in X : xA = A \} \),
- \( \text{Fix}^{-}(A) = \{ x \in X : xA = X \setminus A \} \),
- \( \text{Fix}^{\pm}(A) = \text{Fix}(A) \cup \text{Fix}^{-}(A) \).

**Corollary 4.9.** For a symmetric left-invariant family \( \mathcal{F} \subset \mathcal{P}(X) \), a function \( \varphi : \mathcal{F} \to \mathcal{P}(X) \) belongs to \( \text{End}_{\lambda}(\mathcal{F}) \) if and only if \( \varphi \) is equivariant, symmetric, and monotone.
**Definition 5.2.** A subset $A \subseteq X$ is defined to be

- **$\mathcal{I}$-twin** if $xA =_{\mathcal{I}} X \setminus A$ for some $x \in X$;
- **$\mathcal{I}$-pretwin** if $xA \subseteq X \setminus A \subset_{\mathcal{I}} yA$ for some points $x, y \in X$.

The families of $\mathcal{I}$-twin and $\mathcal{I}$-pretwin subsets of $X$ will be denoted by $\mathcal{T}^\mathcal{I}$ and $\mathcal{pT}^\mathcal{I}$, respectively.

It is clear that $\mathcal{T}^{\{\emptyset\}} = \mathcal{T}$ and $\mathcal{pT}^{\{\emptyset\}} = p\mathcal{T}$.

**Proposition 5.3.** For each subset $A \subseteq X$ the set $\mathcal{I}$-$\text{Fix}^\pm(A)$ is a subgroup in $X$. The set $A$ is $\mathcal{I}$-twin if and only if $\mathcal{I}$-$\text{Fix}(A)$ is a normal subgroup of index 2 in $\mathcal{I}$-$\text{Fix}^\pm(A)$.

**Proof.** If the set $A$ is not $\mathcal{I}$-twin, then $\mathcal{I}$-$\text{Fix}^-(A) = \emptyset$ and then $\mathcal{I}$-$\text{Fix}^\pm(A) = \{x \in X : xA =_{\mathcal{I}} A\}$ is a subgroup of $X$ by the transitivity and left-invariance of the equivalence relation $=_{\mathcal{I}}$.

So, we assume that $A$ is $\mathcal{I}$-twin, which means that $\mathcal{I}$-$\text{Fix}^-(A) \neq \emptyset$. To show that $\mathcal{I}$-$\text{Fix}^\pm(A)$ is a subgroup in $X$, take any two points $x, y \in \mathcal{I}$-$\text{Fix}^\pm(A)$. We claim that $xy^{-1} \in \mathcal{I}$-$\text{Fix}^\pm(A)$.

This is clear if $x, y \in \mathcal{I}$-$\text{Fix}(A) \subseteq \mathcal{I}$-$\text{Fix}^\pm(A)$. If $x \in \mathcal{I}$-$\text{Fix}(A)$ and $y \in \mathcal{I}$-$\text{Fix}^-(A)$, then $xA =_{\mathcal{I}} A, yA =_{\mathcal{I}} X \setminus A$ and thus $A =_{\mathcal{I}} X \setminus y^{-1}A$, which implies $y^{-1}A =_{\mathcal{I}} X \setminus A$. Then $xy^{-1}A =_{\mathcal{I}} x(X \setminus A) = X \setminus xA =_{\mathcal{I}} X \setminus A$, which means that $xy^{-1} \in \mathcal{I}$-$\text{Fix}^-(A) \subseteq \text{Fix}^\pm(A)$.

If $x, y \in \mathcal{I}$-$\text{Fix}^-(A)$, then $xA =_{\mathcal{I}} X \setminus A, y^{-1}A =_{\mathcal{I}} X \setminus A$. This implies that $xy^{-1}A =_{\mathcal{I}} x(X \setminus A) =_{\mathcal{I}} X \setminus xA =_{\mathcal{I}} X \setminus (X \setminus A) =_{\mathcal{I}} A$ and consequently $xy^{-1} \in \mathcal{I}$-$\text{Fix}(A)$.

To show that $\mathcal{I}$-$\text{Fix}(A)$ is a subgroup of index 2 in $\text{Fix}^\pm(A)$, fix any element $g \in \mathcal{I}$-$\text{Fix}^-(A)$. Then for every $x \in \mathcal{I}$-$\text{Fix}(A)$ we get $gxA =_{\mathcal{I}} gA =_{\mathcal{I}} X \setminus A$ and thus $gx \in \mathcal{I}$-$\text{Fix}^-(A)$. This yields $\mathcal{I}$-$\text{Fix}^-(A) = g(\mathcal{I}$-$\text{Fix}(A))$, which means that the subgroup $\mathcal{I}$-$\text{Fix}(A)$ has index 2 in the group $\mathcal{I}$-$\text{Fix}^\pm(A)$. $\blacksquare$

The following proposition shows that the family $\mathcal{T}^\mathcal{I}$ of $\mathcal{I}$-twin sets of a group $X$ is left-invariant.

**Proposition 5.4.** For any $\mathcal{I}$-twin set $A \subseteq X$ and any $x \in X$ the set $xA$ is $\mathcal{I}$-twin and $\mathcal{I}$-$\text{Fix}^-(xA) = x(\mathcal{I}$-$\text{Fix}^-(A))x^{-1}$.

**Proof.** To see that $xA$ is an $\mathcal{I}$-twin set, take any $z \in \mathcal{I}$-$\text{Fix}^-(A)$ and observe that $X \setminus xA = x(X \setminus A) =_{\mathcal{I}} xzA = xzx^{-1}xA$,

which means that $xzx^{-1} \in \mathcal{I}$-$\text{Fix}^-(xA)$ for every $z \in \mathcal{I}$-$\text{Fix}^-(A)$. Hence $\mathcal{I}$-$\text{Fix}^-(xA) = x(\mathcal{I}$-$\text{Fix}^-(A))x^{-1}$. $\blacksquare$

The preceding proposition implies that the family $\mathcal{T}^\mathcal{I}$ of $\mathcal{I}$-twin subsets of $X$ can be considered as an $X$-act with respect to the left action $\cdot : X \times \mathcal{T}^\mathcal{I} \to \mathcal{T}^\mathcal{I}$, $\cdot : (x, A) \mapsto xA$.

of the group $X$. We denote by $[A] = \{xA : x \in X\}$ the orbit of a $\mathcal{I}$-twin set $A \in \mathcal{T}^\mathcal{I}$ and by $[\mathcal{T}^\mathcal{I}] = \{[A] : A \in \mathcal{T}^\mathcal{I}\}$ the orbit space. If $\mathcal{I} = \{\emptyset\}$ is a trivial ideal, then we write $[\mathcal{T}]$ instead of $[\mathcal{T}^\mathcal{I}]$. 
6. Twinic groups

A left-invariant ideal \( I \) on a group \( X \) is called *twinic* if for any subset \( A \subset X \) and points \( x, y \in X \) with \( xA \subset X \setminus A \subset yA \) we get \( A =_{I} B \). In this case the families \( p_{I}^{X} \) and \( T^{I} \) coincide.

A group \( X \) is defined to be *twinic* if it admits a twinic ideal \( I \). It is clear that in a twinic group \( X \) the intersection \( \mathcal{I} \) of all twinic ideals is the smallest twinic ideal in \( X \) called the *twinic ideal* of \( X \). The structure of the twinic ideal \( \mathcal{I} \) can be described as follows.

Let \( \mathcal{I}_{0} = \{ \emptyset \} \) and for each \( n \in \omega \) let \( \mathcal{I}_{n+1} \) be the ideal generated by all sets of the form \( yA \setminus xA \) where \( xA \subset \mathcal{I}_{n} X \setminus A \subset yA \) for some \( A \subset X \) and \( x, y \in X \). By induction it is easy to check that \( \mathcal{I}_{n} \subset \mathcal{I}_{n+1} \subset \mathcal{I} \) is an invariant ideal and hence \( \mathcal{I} = \bigcup_{n \in \omega} \mathcal{I}_{n} \subset \mathcal{I} \) is a well-defined (smallest) twinic ideal on \( X \). This ideal \( \mathcal{I} \) is invariant.

In fact, the above constructive definition of the additive invariant family \( \mathcal{I} \) is valid for each group \( X \). However, \( \mathcal{I} \) is an ideal if and only if the group \( X \) is twinic.

We shall say that a group \( X \) has *trivial twinic ideal* if the trivial ideal \( I = \{ \emptyset \} \) is twinic. This happens if and only if for any subset \( A \subset X \) with \( xA \subset X \setminus A \subset yA \) we get \( xA = X \setminus A = yA \). In this case the twinic ideal \( \mathcal{I} \) of \( X \) is trivial.

The class of twinic groups is sufficiently wide. In particular, it contains all amenable groups. Let us recall that a group \( X \) is called *amenable* if it admits a Banach measure \( \mu : \mathcal{P}(X) \to [0, 1] \), which is a left-invariant probability measure defined on the family of all subsets of \( \mathcal{P}(X) \). In this case the family

\[
\mathcal{N}_{\mu} = \{ A \subset X : \mu(A) = 0 \}
\]

is a left-invariant ideal in \( X \). It is well-known that the class of amenable groups contains all abelian groups and is closed with respect to many operations over groups (see [17]).

A subset \( A \) of an amenable group \( X \) is called *absolutely null* if \( \mu(A) = 0 \) for each Banach measure \( \mu \) on \( X \). The family \( \mathcal{N} \) of all absolutely null subsets is an ideal on \( X \). This ideal coincides with the intersection \( \mathcal{N} = \bigcap_{\mu} \mathcal{N}_{\mu} \) where \( \mu \) runs over all Banach measures of \( X \).

**Theorem 6.1.** Each amenable group \( X \) is twinic. The twinic ideal \( \mathcal{I} \) of \( X \) lies in the ideal \( \mathcal{N} \) of absolute null subsets of \( X \).

**Proof.** It suffices to check that the ideal \( \mathcal{N} \) is twinic. Take any set \( A \subset X \) such that \( xA \subset \mathcal{N} X \setminus A \subset \mathcal{N} yA \) for some \( x, y \in X \). We need to show that \( \mu(yA \setminus xA) = 0 \) for each Banach measure \( \mu \) on \( X \). It follows from \( xA \subset \mathcal{N} X \setminus A \subset yA \) and the invariance of the Banach measure \( \mu \) that

\[
\mu(A) = \mu(xA) \leq \mu(X \setminus A) \leq \mu(yA) = \mu(A)
\]

and hence \( \mu(yA \setminus xA) = \mu(A) - \mu(A) = 0 \). ■

Next, we show that the class of twinic groups also contains some non-amenable groups. The simplest example is the Burnside group \( B(n, m) \) for \( n \geq 2 \) and odd \( m \geq 665 \). We recall that the Burnside group \( B(n, m) \) is generated by \( n \) elements and one relation \( x^{m} = 1 \). Adian [1] proved that for \( n \geq 2 \) and any odd \( m \geq 665 \) the Burnside group
$B(n, m)$ is not amenable (see also [10] for a stronger version of this result). The following theorem implies that each Burnside group, being a torsion group, is twinic. Moreover, its twinic ideal $S$ is trivial!

**Theorem 6.2.** A group $X$ has trivial twinic ideal $S = \{0\}$ if and only if the product $ab$ of any elements $a, b \in X$ belongs to the subsemigroup of $X$ generated by the set $b^\pm \cdot a^\pm$ where $a^\pm = \{a, a^{-1}\}$.

**Proof.** To prove the “if” part, assume that $S \neq \{0\}$. Then $S_{n+1} \neq \{0\} = S_n$ for some $n \in \omega$ and we can find a subset $A \subset X$ and points $a, b \in X$ such that $a^{-1}A \subset X \setminus A \subset bA$ but $a^{-1}A \neq bA$. Consider the subsemigroup $Fix_\subset(A) = \{x \in X : xA \subset A\} \subset X$ and observe that $b^{-1}a^{-1} \in Fix_\subset(A)$. The inclusion $a^{-1}A \subset X \setminus A$ implies $a^{-1}A \cap A = \emptyset$, which is equivalent to $A \cap aA = \emptyset$ and yields $aA \subset X \setminus A \subset bA$. Then $b^{-1}a \in Fix_\subset(A)$.

Now consider the chain of equivalences

$$X \setminus A \subset bA \iff A \cup bA = X \iff b^{-1}A \cup A = X \iff X \setminus A \subset b^{-1}A$$

and combine the last inclusion with $aA \cup a^{-1}A \subset X \setminus A$ to obtain $ba, ba^{-1} \in Fix_\subset(A)$. Now we see that the subsemigroup $S$ of $X$ generated by the set $\{1, ba, ba^{-1}, b^{-1}a, b^{-1}a^{-1}\}$ lies in $Fix_\subset(A)$. Observe that $b^{-1}a^{-1}A \subset A$ implies $abA \not\subset A$, $ab \not\in Fix_\subset(A) \supset S$, and finally $ab \not\in S$. This completes the proof of the “if” part.

To prove the “only if” part, assume that the group $X$ contains elements $a, b$ whose product $ab$ does not belong to the subsemigroup generated by $b^\pm a^\pm$ where $a^\pm = \{a, a^{-1}\}$ and $b^\pm = \{b, b^{-1}\}$. Then $ab$ also does not belong to the subsemigroup $S$ generated by $\{1\} \cup b^\pm a^\pm$. Observe that $a^\pm S = S^{-1}a^\pm$ and $b^\pm S^{-1} = Sb^\pm$.

We claim that

$$S \cap a^\pm S = \emptyset \quad \text{and} \quad S \cap Sb^\pm = \emptyset. \quad (6.1)$$

Assuming that $S \cap a^\pm S \neq \emptyset$ we would find a point $s \in S$ such that $as \in S$ or $a^{-1}s \in S$. If $as \in S$, then $bs^{-1} = b(ab^{-1}s) a \subset Sb^\pm a \subset S$ and hence $b = bs^{-1}s \in S \cdot S \subset S$. Then $a^\pm = b(b^{-1}a^\pm) \subset S \cdot S \subset S$, $b^\pm = (b^\pm a) a^{-1} \subset S \cdot S \subset S$ and finally $ab \in S \cdot S \subset S$, which contradicts $ab \not\in S$. By analogy we can treat the case $a^{-1}s \in S$ and also prove that $S \cap Sb^\pm = \emptyset$.

Consider the family $P$ of all pairs $(A, B)$ of disjoint subsets of $X$ such that

(a) $a^\pm A \subset B$ and $b^\pm B \subset A$;
(b) $S^{-1}B \subset B$;
(c) $1 \in A$, $ab \in B$.

The family $P$ is partially ordered by the relation $(A, B) \leq (A', B')$ defined by $A \subset A'$ and $B \subset B'$.

We claim that the pair $(A_0, B_0) = (S \cup Sb^\pm ab, S^{-1}a^\pm \cup S^{-1}ab)$ belongs to $P$. Indeed,

$$a^\pm A_0 = a^\pm S \cup a^\pm Sb^\pm ab \subset S^{-1}a^\pm \cup S^{-1}a^\pm b^\pm ab \subset S^{-1}a^\pm \cup S^{-1}ab \subset B_0.$$

By analogy we check that $b^\pm B_0 \subset A_0$. Items (b), (c) trivially follow from the definition of $A_0$ and $B_0$. It remains to check that the sets $A_0$ and $B_0$ are disjoint.

This will follow as soon as we check that

(d) $S \cap S^{-1}a^\pm = \emptyset$;
(e) $S \cap S^{-1}ab = \emptyset$;
Applying Theorem 6.2, we conclude that the group $Sb^±ab ∩ S^{-1}a^± = ∅$;

(g) $Sb^±ab ∩ S^{-1}ab = ∅$.

Items (d) and (g) follow from (6.1). Item (e) follows from (6.1). Thus the partially ordered set $P$ is not empty and we can apply Zorn's Lemma to find a maximal pair $(A, B) ≥ (A_0, B_0)$ in $P$. We claim that $A ∪ B = X$. Assuming the converse, we could take any point $x ∈ X \setminus (A ∪ B)$ and put $A′ = A ∪ Sx, B′ = B ∪ a^±Sx$. It is clear that $a^±A′ ⊂ B′$ and $b^±B′ ⊂ A′, S^{-1}B′ = S^{-1}B ∪ S^{-1}a^±Sx ⊂ B ∪ a^±Sx = B′, 1 ∈ A ⊂ A′$ and $ab ∈ B ⊂ B′$.

Now we see that the inclusion $(A′, B′) ∈ P$ will follow as soon as we check that $A′ ∩ B′ = ∅$. The choice of $x ∉ B = S^{-1}B$ guarantees that $Sx ∩ B = ∅$. Assuming that $a^±Sx ∩ A ≠ ∅$, we would conclude that $x ∈ S^{-1}a^±A ⊂ S^{-1}B ⊂ B$, which contradicts the choice of $x$. Finally, the sets $Sx$ and $a^±Sx$ are disjoint because of the property (6.1) of $S$. Thus we obtain a contradiction: $(A′, B′) ∈ P$ is strictly greater than the maximal pair $(A, B)$. This contradiction shows that $X = A ∪ B$ and consequently $aA ⊂ X \setminus A = B ⊂ bA$, which means that the set $A$ is pretwin and so $bA \setminus aA ∈ \mathfrak{II}_1 ⊂ \mathfrak{II}$. Since $1 ∈ A \setminus b^{-1}a^{-1}A$, we conclude that $bA \setminus a^{-1}A ∋ b$ is not empty and thus $\mathfrak{II} ≠ \{∅\}$. ■

We recall that a group $X$ is periodic (or a torsion group) if each element $x ∈ X$ has finite order (which means that $x^n = e$ for some $n ∈ \mathbb{N}$). We shall say that a group $X$ has periodic commutators if for any $x, y ∈ G$ the commutator $[x, y] = xyx^{-1}y^{-1}$ has finite order in $X$. It is interesting to note that this condition is strictly weaker than the requirement for $X$ to have periodic commutator subgroup $X′$ (we recall that the commutator subgroup $X′$ coincides with the set of finite products of commutators; see [6]).

**Proposition 6.3.** Each group $X$ with periodic commutators has trivial twinic ideal $\mathfrak{II} = \{∅\}$.

**Proof.** Since $X$ has periodic commutators, for any points $x, y ∈ X$ there is a number $n ∈ \mathbb{N}$ such that

$$xyx^{-1}y^{-1} = (xyx^{-1}x^{-1})^{-1} = (xyx^{-1}x^{-1})^n$$

and thus $xy = (xyx^{-1}x^{-1})^n · yx$ belongs to the semigroup generated by the set $y^± · x^±$. Applying Theorem 6.2 we conclude that the group $X$ has trivial twinic ideal $\mathfrak{II} = \{∅\}$. ■

We recall that a group $G$ is called abelian-by-finite (resp. finite-by-abelian) if $G$ contains a normal abelian (resp. finite) subgroup $H ⊂ G$ with finite (resp. abelian) quotient $G/H$. Observe that each finite-by-abelian group has periodic commutators and hence has trivial twinic ideal $\mathfrak{II}$.

In contrast, any abelian-by-finite group, being amenable, is twinic but its twinic ideal $\mathfrak{II}$ need not be trivial. The simplest counterexample is the isometry group $Iso(\mathbb{Z})$ of the group $\mathbb{Z}$ of integers endowed with the Euclidean metric.

**Example 6.4.** The abelian-by-finite group $X = Iso(\mathbb{Z})$ is twinic. Its twinic ideal $\mathfrak{II}$ coincides with the ideal $[X]^{< ω}$ of all finite subsets of $X$.

**Proof.** Let $a : x ↦ x + 1$ be the translation and $b : x ↦ −x$ be the inversion of the group $\mathbb{Z}$. It is easy to see that the elements $a, b$ generate the isometry group $X = Iso(\mathbb{Z})$.
and satisfy the relations $b^2 = 1$ and $bab^{-1} = a^{-1}$. Let $Z = \{a^n : n \in \mathbb{Z}\}$ be the cyclic subgroup of $X$ generated by the translation $a$. This subgroup $Z$ has index 2 in $X = \mathbb{Z} \cup Zb$.

First we show that the ideal $\mathcal{I} = [X]<\omega$ of finite subsets of $X$ is twinic. Let $A \subset X$ be a subset with $xA \subset_{\mathcal{I}} X \setminus A \subset_{\mathcal{I}} yA$ for some $x, y \in X$. We need to show that $yA =_{\mathcal{I}} xA$.

We consider three cases.

(1) $x, y \in Z$. In this case the elements $x, y$ commute. The $\mathcal{I}$-inclusion $xA \subset_{\mathcal{I}} yA$ implies $y^{-1}xA \subset_{\mathcal{I}} A$. We claim that $y^{-1}xA \supset_{\mathcal{I}} A$. Observe that the $\mathcal{I}$-inclusion $xA \subset_{\mathcal{I}} X \setminus A$ is equivalent to $xA \cap A \in \mathcal{I}$ and to $A \cap x^{-1}A \in \mathcal{I}$, which implies $x^{-1}A \subset_{\mathcal{I}} X \setminus A$. By analogy, $X \cap yA$ is equivalent to $yA \cap A =_{\mathcal{I}} X$ and to $A \cup y^{-1}A =_{\mathcal{I}} X$, which implies $X \setminus yA =_{\mathcal{I}} y^{-1}A$. Then $x^{-1}A \subset_{\mathcal{I}} X \setminus A \subset_{\mathcal{I}} y^{-1}A$ implies $yx^{-1}A \subset_{\mathcal{I}} A$ and by the left-invariance of $\mathcal{I}$, $A \subset_{\mathcal{I}} xy^{-1}A = y^{-1}xA$ (we recall that the elements $x, y$ commute). Therefore, $y^{-1}xA =_{\mathcal{I}} A$ and hence $xA =_{\mathcal{I}} yA$.

(2) $x \in Z$ and $y \in X \setminus Z$. Repeating the argument from the preceding case, we can show that $xA \subset_{\mathcal{I}} X \setminus A$ implies $x^{-1}A \subset_{\mathcal{I}} X \setminus A$. Then we get the chain of $\mathcal{I}$-inclusions

$$xA \subset_{\mathcal{I}} X \setminus A \subset_{\mathcal{I}} yA \subset_{\mathcal{I}} y(xA) = y(x\setminus A) \subset_{\mathcal{I}} yxyA =_{\mathcal{I}} xA,$$

where the last $\mathcal{I}$-equality follows from case (1) since $x, yxy \in Z$. Now we see that $xA =_{\mathcal{I}} yA$.

(3) $x \notin Z$. Then $xA \subset_{\mathcal{I}} X \setminus A \subset_{\mathcal{I}} yA$ implies

$$x^{-1}ba = bx^{-1}bA = bxA \subset_{\mathcal{I}} X \setminus bA \subset_{\mathcal{I}} byA = y^{-1}bA.$$Since $x^{-1}b \in Z$, cases (1), (2) imply the $\mathcal{I}$-equality $x^{-1}bA =_{\mathcal{I}} y^{-1}bA$. Shifting this equality by $b$, we see that $xA = bx^{-1}bA =_{\mathcal{I}} by^{-1}bA = yA$.

This completes the proof of the twinic property of the ideal $\mathcal{I} = [X]<\omega$. Then $\mathcal{I} \subset [X]<\omega$. Since $[X]<\omega$ is the smallest non-trivial left-invariant ideal on $X$, the equality $\mathcal{I} = [X]<\omega$ will follow as soon as we find a non-empty set in the ideal $\mathcal{I}$.

For this consider the subset $A = \{a^{n+1}, ba^{-n} : n \geq 0\} \subset X$ and observe that $X \setminus A = \{a^{-n}, ba^{n+1} : n \geq 0\} = bA$, witnessing that $A \in \mathcal{I}$. Observe also that $aA = \{a^{n+2}, aba^{-n} : n \geq 0\} = \{a^{n+2}, ba^{-n} : n \geq 0\} \subset A$ and thus $baA \subset X \setminus A = bA$. Then $\emptyset \neq baA \setminus bA \in \mathcal{I}_1 \subset \mathcal{I}$ witnesses that the twinic ideal $\mathcal{I}$ is not trivial.

Next, we present an (expected) example of a group which is not twinic.

**Example 6.5.** The free group $F_2$ with two generators is not twinic.

**Proof.** Assume that the group $X = F_2$ is twinic and let $\mathcal{I}$ be the twinic ideal of $F_2$. Let $a, b$ be the generators of the free group $F_2$. Each element $w \in F_2$ can be represented by a word in the alphabet $\{a, a^{-1}, b, b^{-1}\}$. The word of the smallest length representing $w$ is called the irreducible representation of $w$. The irreducible word representing the neutral element of $F_2$ is the empty word. Let $A$ (resp. $B$) be the set of words whose irreducible representations start with $a$ or $a^{-1}$ (resp. $b$ or $b^{-1}$). Consider the subset

$$C = \{a^{2n}w : w \in B \cup \{e\}, n \in \mathbb{Z}\} \subset F_2$$
and observe that $abaC \subset X \setminus C = aC$. Then $aC \setminus abaC \in \mathcal{I}_1$ by the definition of the subideal $\mathcal{I}_1 \subset \mathcal{I}$. Observe that $a^3baC \subset aC \setminus abaC$ and thus $a^3baC \in \mathcal{I}_1$. Then also
$C \in \mathcal{I}_1$ and $X \setminus C = aC \in \mathcal{I}_1$ by the left-invariance of $\mathcal{I}_1$. By the additivity of $\mathcal{I}_1$, we finally get $X = C \cup (X \setminus C) \in \mathcal{I}_1 \subset \mathcal{I}$, which is the desired contradiction.

Next, we prove some permanence properties of the class of twinic groups.

**Proposition 6.6.** Let $f : X \to Y$ be a surjective group homomorphism. If the group $X$ is twinic, then so is the group $Y$.

**Proof.** Let $\mathcal{I}$ be the twinic ideal of $X$. It is easy to see that $I = \{ B \subset Y : f^{-1}(B) \in \mathcal{I} \}$ is a left-invariant ideal on the group $Y$. We claim that it is twinic. Given any subset $A \subset Y$ with $xA \subset \mathcal{I}$ and $x \notin yA$ for some $x, y \in Y$, let $B = f^{-1}(A)$ and observe that $x'B \subset \mathcal{I} \setminus B \subset \mathcal{I}$ for some points $x' \in f^{-1}(x)$ and $y' \in f^{-1}(y)$. The twinic property of the twinic ideal $\mathcal{I}$ guarantees that $f^{-1}(yA \setminus xA) = y'B \setminus x'B \in \mathcal{I}$, which implies $yA \setminus xA \in \mathcal{I}$ and hence $xA = xA \setminus yA$.

**Problem 6.7.** Is a subgroup of a twinic group twinic? Is the product of two twinic groups twinic?

For groups with trivial twinic ideal the first part of this problem has an affirmative solution, which follows from the characterization Theorem 6.2.

**Proposition 6.8.**

1. The class of groups with trivial twinic ideal is closed with respect to taking subgroups and quotient groups.
2. A group $X$ has trivial twinic ideal if and only if any 2-generated subgroup of $X$ has trivial twinic ideal.

## 7. 2-Cogroups

It follows from Proposition 5.3 that for a twin subset $A$ of a group $X$ the stabilizer $\text{Fix}(A)$ of $A$ is completely determined by the subset $\text{Fix}^-(A)$ because $\text{Fix}(A) = x \cdot \text{Fix}^-(A)$ for each $x \in \text{Fix}^-(A)$. Therefore, the subset $\text{Fix}^-(A)$ carries all the information about the pair $(\text{Fix}^-(A), \text{Fix}(A))$. The sets $\text{Fix}^-(A)$ are particular cases of so-called 2-cogroups defined as follows.

**Definition 7.1.** A subset $K$ of a group $X$ is called a 2-cogroup if for every $x \in K$ the shift $xK = Kx$ is a subgroup of $X$, disjoint from $K$.

By the index of a 2-cogroup $K$ in $X$ we understand the cardinality $|X/K|$ of the set $X/K = \{ Kx : x \in X \}$.

2-cogroups can be characterized as follows.

**Proposition 7.2.** A subset $K$ of a group $X$ is a 2-cogroup in $X$ if and only if there is a (unique) subgroup $H^\pm$ of $X$ and a subgroup $H \subset H^\pm$ of index 2 such that $K = H^\pm \setminus H$ and $H = K \cdot K$.

**Proof.** If $K$ is a 2-cogroup, then for every $x \in K$ the shift $H = xK = Kx$ is a subgroup of $X$ disjoint from $K$. It follows that $K = x^{-1}H = Hx^{-1}$. Since $x^{-1} \in x^{-1}H = K$, the shift $x^{-1}K = Kx^{-1}$ is a subgroup of $X$ according to the definition
of a 2-cogroup. Consequently, $x^{-1}Kx^{-1}K = x^{-1}K$ and $Hx^{-1}x^{-1}Hx^{-1} = Kx^{-1}K = K = Hx^{-1}$. This implies $x^{-2} \in H$ and $x^2 \in H$. Consequently, $xH = x^{-1}x^2H = x^{-1}H = K = Hx^{-1} = Hx^2x^{-1} = Hx$.

Now we are able to show that $H^\pm = H \cup K$ is a group. Indeed,

$$(H \cup K) \cdot (H \cup K)^{-1} \subset HH^{-1} \cup HK^{-1} \cup KH^{-1} \cup KK^{-1} \subset H \cup HH \cup xHH \cup Hx^{-1}xH = H \cup K \cup K \cup H = H^\pm.$$ 

Since $K = Hx = xH$, the subgroup $H = K \cdot K$ has index 2 in $H^\pm$. The uniqueness of the pair $(H^\pm, H)$ follows from the fact that $H = K \cdot K$ and $H^\pm = K \cup K$. This completes the proof of the “only if” part.

To prove the “if” part, assume that $H^\pm$ is a subgroup of $X$ and $H \cap H^\pm$ is a subgroup of index 2 such that $K = H^\pm \setminus H$. Then for every $x \in K$ the shift $xK = Kx = H$ is a subgroup of $X$ disjoint from $K$. This means that $K$ is a 2-cogroup. ■

Proposition 7.2 implies that for each 2-cogroup $K \subset X$ the set $K^\pm = K \cup KK$ is a subgroup of $X$ and $KK$ is a subgroup of index 2 in $K^\pm$.

We shall denote by $\mathcal{K}$ the family of all 2-cogroups in $X$. It is partially ordered by the inclusion relation $\subset$ and is considered as an $X$-act endowed with the conjugating action

$$\cdot : X \times \mathcal{K} \to \mathcal{K}, \quad \cdot : (x, K) \mapsto xKx^{-1},$$

denote the orbit space of $X$.

For each 2-cogroup $K \in \mathcal{K}$ let $\text{Stab}(K) = \{x \in X : xKx^{-1} = K\}$ be the stabilizer of $K$ and $[K] = \{xKx^{-1} : x \in X\}$ be the orbit of $K$. Let $[\mathcal{K}] = \{[K] : K \in \mathcal{K}\}$ denote the orbit space of $\mathcal{K}$ under the action of the group $X$.

A cogroup $K \in \mathcal{K}$ is called normal if $xKx^{-1} = K$ for all $x \in X$. This is equivalent to saying that $\text{Stab}(K) = X$.

Since for each twin subset $A \subset X$ the set $\text{Fix}^{-}(A)$ is a 2-cogroup, the function

$$\text{Fix}^{-} : \mathcal{T} \to \mathcal{K}, \quad \text{Fix}^{-} : A \mapsto \text{Fix}^{-}(A),$$

is well-defined and equivariant according to Proposition 5.4. A similar equivariant function

$$\mathcal{I}\text{-Fix}^{-} : \mathcal{T}^\mathcal{I} \to \mathcal{K}, \quad \mathcal{I}\text{-Fix}^{-} : A \mapsto \mathcal{I}\text{-Fix}^{-}(A),$$

can be defined for any left-invariant ideal $\mathcal{I}$ on a group $X$.

Let $\mathcal{\hat{K}}$ denote the set of maximal elements of the partially ordered set $(\mathcal{K}, \subset)$. The following proposition implies that $\mathcal{\hat{K}}$ lies in the image $\text{Fix}^{-}(\mathcal{T})$ and is cofinal in $\mathcal{K}$.

**Proposition 7.3.**

1. For any linearly ordered family $\mathcal{C} \subset \mathcal{K}$ of 2-cogroups in $X$ the union $\bigcup \mathcal{C}$ is a 2-cogroup in $X$.
2. Each 2-cogroup $K \in \mathcal{K}$ lies in a maximal 2-cogroup $\mathcal{\hat{K}} \in \mathcal{\hat{K}}$.
3. For each maximal 2-cogroup $K \in \mathcal{\hat{K}}$ there is a twin subset $A \in \mathcal{T}$ with $K = \text{Fix}^{-}(A)$.

**Proof.** 1. Let $\mathcal{C} \subset \mathcal{K}$ be a linearly ordered family of 2-cogroups of $X$. Since each 2-cogroup $C \in \mathcal{C}$ is disjoint from the group $C \cdot C$ and $C = C \cdot C \cdot C$, we see that the union $K = \bigcup \mathcal{C}$ is disjoint from the union $\bigcup_{C \in \mathcal{C}} C \cdot C = K \cdot K$ and $K = \bigcup_{C \in \mathcal{C}} C = \bigcup_{C \in \mathcal{C}} C \cdot C \cdot C = K \cdot K \cdot K$, witnessing that $K$ is a 2-cogroup.
2. Since each chain in \( K \) is upper bounded, Zorn’s Lemma guarantees that each 2-cogroup of \( X \) lies in a maximal 2-cogroup.

3. Given a maximal 2-cogroup \( K \in \hat{K} \), consider the subgroups \( K \cdot K \) and \( K^{\pm} = K \cup KK \)
of \( X \) and choose a subset \( S \subset G \) meeting each coset \( K^{\pm} \cdot x, x \in X \), in a single point.
Consider the set \( A = K \cdot K \cdot S \) and note that \( X \setminus A = KS = xA \) for each \( x \in K \), which
means that \( K \subset \text{Fix}^{-} (A) \). The maximality of \( K \) guarantees that \( K = \text{Fix}^{-} (A) \). ■

It should be mentioned that in general \( \text{Fix}^{-} (T) \neq \mathcal{K} \).

**Example 7.4.** For any twin subset \( A \) in the 4-element group \( X = C_{2} \oplus C_{2} \) the group
\( \text{Fix} (A) \) is not trivial. Consequently, each singleton \( \{a\} \subset X \setminus \{e\} \) is a 2-cogroup that does not belong to the image \( \text{Fix}^{-} (T) \).

A left-invariant subfamily \( F \subset T \) is called

- \( \hat{K} \)-covering if \( \hat{K} \subset \text{Fix}^{-} (F) \) (this means that for each maximal 2-cogroup \( K \in \hat{K} \) there
is a twin set \( A \in F \) with \( \text{Fix}^{-} (A) = K \));
- minimal \( \hat{K} \)-covering if \( F \) coincides with each left-invariant \( \hat{K} \)-covering subfamily of \( F \).

Proposition 7.3\(^{(3)} \) implies that the family
\[
\hat{T} = \{ A \in T : \text{Fix}^{-} (A) \in \hat{K} \}
\]
is \( \hat{K} \)-covering.

**Proposition 7.5.** For any function \( f \in \text{End}_{\lambda} (P (X)) \) the family \( f (\hat{T}) \) is \( \hat{K} \)-covering.

**Proof.** The equivariance of the function \( f \) and the left-invariance of the family \( \hat{T} \) imply
the left-invariance of the family \( f (\hat{T}) \). To see that \( f (\hat{T}) \) is \( \hat{K} \)-covering, fix any maximal 2-cogroup \( K \in \hat{K} \) and using Proposition 7.3\(^{(3)} \) find a twin set \( A \subset X \) with \( \text{Fix}^{-} (A) = K \). We
claim that \( \text{Fix}^{-} (f(A)) = \text{Fix}^{-} (A) = K \). By Corollary 4.4\(^{(2)} \) the function \( f \) is equivariant
and symmetric. Then for every \( x \in \text{Fix}^{-} (A) \), applying \( f \) to the equality \( xA = X \setminus A \), we obtain
\[
x f(A) = f(xA) = f(X \setminus A) = X \setminus f(A),
\]
which means that \( x \in \text{Fix}^{-} (f(A)) \) and thus \( \text{Fix}^{-} (A) \subset \text{Fix}^{-} (f(A)) \). Now the maximality
of the 2-cogroup \( \text{Fix}^{-} (A) \) guarantees that \( \text{Fix}^{-} (f(A)) = \text{Fix}^{-} (A) \). ■

**Remark 7.6.** In Theorem 17.1\(^{(2)} \) we shall show that for a twinic group \( X \) and a function
\( f \in K (\text{End}_{\lambda} (P (X))) \) from the minimal ideal of \( \text{End}_{\lambda} (P (X)) \) the family \( f (\hat{T}) \) is minimal
\( \hat{K} \)-covering.

For each 2-cogroup \( K \subset X \) consider the families
\[
\mathcal{T}_{K} = \{ A \in T : \text{Fix}^{-} (A) = K \} \quad \text{and} \quad \mathcal{T}_{[K]} = \{ A \in T : \exists x \in X \text{ with } \text{Fix}^{-} (xA) = K \}.
\]
The following proposition describing the structure of minimal \( \hat{K} \)-covering families can be easily derived from the definitions.

**Proposition 7.7.** A left-invariant subfamily \( F \subset \hat{T} \) is minimal \( \hat{K} \)-covering if and only
if for each \( K \in \hat{K} \) there is a set \( A \in F \) such that \( F \cap \mathcal{T}_{[K]} = [A] \).
8. The characteristic group $H(K)$ of a 2-cogroup $K$

In this section we introduce an important notion of the characteristic group $H(K)$ of a 2-cogroup $K$ in a group $X$ and reveal the algebraic structure of the characteristic groups of maximal 2-cogroups.

Observe that for each 2-cogroup $K \subset X$ its stabilizer $\text{Stab}(K) = \{ x \in X : xKx^{-1} = K \}$ contains $KK$ as a normal subgroup. So, we can consider the quotient group $H(K) = \text{Stab}(K)/KK$ called the characteristic group of the 2-cogroup $K$. Characteristic groups will play a crucial role for description of the structure of maximal subgroups of the minimal ideal of the semigroup $\lambda(X)$.

Observe that for a normal 2-cogroup $K \in \mathcal{K}$ the characteristic group $H(K)$ is equal to the quotient group $X/KK$.

The characteristic group $H(K)$ of each maximal 2-cogroup $K \subset X$ has a remarkable algebraic property: it is a 2-group with a unique 2-element subgroup. Such finite groups were classified in [20, 5.3.6].

Let us recall that a group $G$ is called a 2-group if the order of each element of $G$ is a power of 2. Let us recall some standard examples of 2-groups.

We denote by $Q_8 = \{1, i, j, k, -1, -i, -j, -k \}$ the group of quaternions. It is a multiplicative subgroup of the real algebra $\mathbb{H}$ of quaternions. The algebra $\mathbb{H}$ contains the field of complex numbers as a subalgebra. For each $n \in \omega$ let

$$C_{2^n} = \{ z \in \mathbb{C} : z^{2^n} = 1 \}$$

be the cyclic group of order $2^n$. The multiplicative subgroup $Q_{2^n} \subset \mathbb{H}$ generated by the set $C_{2^n} \cup Q_8$ is called the group of generalized quaternions (see [19 §5.3]). The subgroup $C_{2^n-1}$ has index 2 in $Q_{2^n}$ and each element of $Q_{2^n} \setminus C_{2^n-1}$ has order 4. According to our definition, $Q_{2^n} = Q_8$ for $n \leq 3$. For $n \geq 3$ the group $Q_{2^n}$ has the presentation

$$\langle x, y | x^2 = y^{2^{n-2}}, x^4 = 1, xyx^{-1} = y^{-1} \rangle.$$

The unions

$$C_{2^\omega} = \bigcup_{n \in \omega} C_{2^n} \quad \text{and} \quad Q_{2^\omega} = \bigcup_{n \in \omega} Q_{2^n}$$

are called the quasicyclic 2-group and the infinite group of generalized quaternions, respectively.

**Theorem 8.1.** A group $G$ is isomorphic to $C_{2^n}$ or $Q_{2^n}$ for some $1 \leq n \leq \infty$ if and only if $G$ is a 2-group with a unique element of order 2.

**Proof.** The “only if” part is trivial. To prove the “if” part, assume that $G$ is a 2-group with a unique element of order 2. Denote this element by $-1$ and let 1 be the neutral element of $G$. If the group $G$ is finite, then by Theorem 5.3.6 of [19], $G$ is isomorphic to $C_{2^n}$ or $Q_{2^n}$ for some $n \in \mathbb{N}$. So, we assume that $G$ is infinite.

Since $-1$ is a unique element of order 2, the cyclic subgroup $\{ -1, 1 \}$ is the maximal 2-elementary subgroup of $G$ (we recall that a group is 2-elementary if it can be written as the direct sum of 2-element cyclic groups). Now Theorem 2 of [21] implies that the group $G$ contains a normal abelian subgroup $H$ of finite index. Since $G$ is infinite, so is the subgroup $H$. Let $\hat{H}$ be a maximal subgroup of $G$ that contains $H$. 
We claim that $H = \tilde{H}$ and $H$ is isomorphic to the quasicyclic 2-group $C_{2\infty}$. Since $H$ is a 2-group, the unique element $-1$ of the group $G$ belongs to $H$. Let $f : \{-1,1\} \to C_2$ be the unique isomorphism. Since the group $C_{2\infty}$ is injective, by Baer’s Theorem [19, 4.1.2], the homomorphism $f : \{-1,1\} \to C_2 \subset C_{2\infty}$ extends to a homomorphism $\tilde{f} : \tilde{H} \to C_{2\infty}$. We claim that $\tilde{f}$ is an isomorphism. Indeed, the kernel $\tilde{f}^{-1}(1)$ of $\tilde{f}$ is trivial since it is a 2-group and contains no element of order 2. So, $\tilde{f}$ is injective and then $\tilde{f}(\tilde{H})$ coincides with $C_{2\infty}$, being an infinite subgroup of $C_{2\infty}$. For the same reason, $\tilde{f}(H) = C_{2\infty}$. Consequently, $\tilde{H} = \tilde{H}$ is isomorphic to $C_{2\infty}$.

If $G = H$, then $G$ is isomorphic to $C_{2\infty}$. So, it remains to consider the case of non-abelian group $G \neq H$.

**Claim 8.2.** For every $a \in H$ and $b \in G \setminus H$ we get $b^2 = -1$ and $bab^{-1} = a^{-1}$.

**Proof.** The maximality of the abelian subgroup $H$ implies that $bx \neq xb$ for some element of $H$. Since $H$ is quasicyclic, we can assume that the element $x$ has order $\geq 8$ and $a$ belongs to the cyclic subgroup generated $\langle x \rangle$.

Using the fact that the maximal abelian subgroup $H$ has finite index in $G$, one can show that the group $G$ is locally finite. Consequently, the subgroup $F = \langle b, x \rangle$ generated by the set $\{b, x\}$ is finite. By Theorem 5.3.6 of [19], this subgroup is isomorphic to $Q_{2^n}$ for some $n \geq 4$. Analyzing the properties of the group $Q_{2^n}$ we see that $b^2 = -1$ and $byb^{-1} = y^{-1}$ for all $y \in \langle x \rangle$. In particular, $bab^{-1} = a^{-1}$. □

Next, we show that the subgroup $H$ has index 2 in $G$. This will follow as soon as we show that for each $x, y \in G \setminus H$ we get $xy \in H$. Observe that for every $a \in H$ we get $xyay^{-1}bx^{-1} = xa^{-1}x^{-1} = a$, which means that $xy$ commutes with each element of $H$ and hence $xy \in H$ by the maximality of $H$. Now take any elements $b \in G \setminus H$ and $q \in Q_{2\infty} \setminus C_{2\infty}$. Extend the isomorphism $\tilde{f} : H \to C_{2\infty}$ to a map $\tilde{f} : G \to Q_{2\infty}$ letting $\tilde{f}(bh) = q \cdot \tilde{f}(h)$ for $h \in H$. Claim 8.2 implies that $\tilde{f}$ is a well-defined isomorphism between $G = H \cup bH$ and $Q_{2\infty}$. □

**Theorem 8.3.** For each maximal 2-cogroup $K \in \hat{\mathcal{K}}$ in a group $X$ the characteristic group $H(K) = \text{Stab}(K)/KK$ is isomorphic either to $C_{2^n}$ or to $Q_{2^n}$ for some $1 \leq n \leq \infty$.

**Proof.** This theorem will follow from Theorem 8.1 as soon as we check that $H(K)$ is a 2-group with a unique element of order 2.

Let $q : \text{Stab}(K) \to H(K)$ be the quotient homomorphism. Take any element $x \in K$ and consider its image $d = q(x)$. Since $K = xKK$, the image $q(K) = \{d\}$ is a singleton. Taking into account that $x \notin KK$ and $x^2 \in KK$, we see that the element $d$ has order 2 in $H(K)$. We claim that any other element $a$ of order 2 in $H(K)$ is equal to $d$. Assume towards a contradiction that some element $a \neq d$ of $H(K)$ has order 2.

Let $C^\pm$ be the subgroup of $H(K)$ generated by the elements $a, d$, and $C$ be the cyclic subgroup generated by the product $ad$. We claim that $d \notin C$. Assuming conversely that $d \in C$, we conclude that $d = (ad)^n$ for some $n \in \mathbb{Z}$. Then $a = add = ad(ad)^n = (ad)^{n+1} \in C$ and consequently $a = d$ (because cyclic groups contain at most one element of order 2). Therefore $d \notin C$. It is clear that $C^\pm = C \cup dC$, which means that the subgroup $C$ has index 2 in $C^\pm$. 
Consider the subgroups $H^\pm = q^{-1}(C^\pm)$, $H = q^{-1}(C)$ and observe that the 2-cogroup $H^\pm \setminus H$ is strictly larger than $K$, which contradicts $K \in \hat{K}$.

Since $d$ is a unique element of order 2 in $H(K)$, the cyclic subgroup $D = \{d, d^2\}$ generated by $d$ is normal in $H(K)$. Consequently, for each non-trivial subgroup $G \subset H(K)$ the product $D \cdot G = G \cdot D$ is a subgroup in $H(K)$. Now we see that $G$ must contain $d$. Otherwise, $dG$ would be a 2-cogroup in $H(K)$ and its preimage $q^{-1}(dG)$ would be a 2-cogroup in $X$ that contains the 2-cogroup $K$ as a proper subset, which is impossible as $K$ is a maximal 2-cogroup in $X$.

Therefore each non-trivial subgroup of $H(K)$ contains $d$. This implies that each element $x \in H(K)$ has finite order which is a power of 2, witnessing that $H(K)$ is a 2-group with a single element of order 2. ■

9. Twin-generated topologies on groups

In this section we study so-called twin-generated topologies on groups. The information obtained in this section will be used in Section 20 to study the topological structure of maximal subgroups of the minimal ideal of the superextension $\lambda(X)$.

Given a twin subset $A$ of a group $X$ consider the topology $\tau_A$ on $X$ generated by the subbase consisting of the right shifts $Ax$, $x \in X$. In the following proposition by the weight of a topological space we understand the smallest cardinality of a subbase of its topology.

**Proposition 9.1.**

1. The topology $\tau_A$ turns $X$ into a right-topological group.
2. If $Ax = xa$ for all $x \in \text{Fix}^-(A)$, then the topology $\tau_A$ is zero-dimensional.
3. The topology $\tau_A$ is $T_1$ if and only if the intersection $\bigcap_{x \in A} Ax^{-1}$ is a singleton.
4. The weight of the space $(X, \tau_A)$ does not exceed the index of the subgroup $\text{Fix}(A^{-1})$ in $X$.

**Proof.** 1. It is clear that the topology $\tau_A$ is right-invariant.

2. If $Ax = xa$ for all $x \in \text{Fix}^-(A)$, then the set $X \setminus A$ is open in the topology $\tau_A$ because $X \setminus A = xA = Ax$ for any $x \in \text{Fix}^-(A)$. Consequently, $A$ is an open-and-closed subbasic set. Now we see that the space $(X, \tau_A)$ has a base consisting of open-and-closed subsets, which means that it is zero-dimensional.

3. If the topology $\tau_A$ is $T_1$, then the intersection $\bigcap_{a \in A} Aa^{-1}$ of all open neighborhoods of the neutral element $e$ of $X$ consists of the single point $e$. Assuming conversely that $\bigcap_{a \in A} Aa^{-1} = \{e\}$, for any two distinct points $x, y \in X$ we can find a shift $Aa^{-1}$, $a \in A$, that contains $e$ but not $yx^{-1}$. Then the shift $Aa^{-1}x$ is an open subset of $(X, \tau)$ that contains $x$ but not $y$, witnessing that the space $(X, \tau_A)$ is $T_1$.

4. To estimate the weight of the space $(X, \tau_A)$, choose a subset $S \subset X$ meeting each coset $x\text{Fix}(A^{-1})$, $x \in X$, in a single point (here $\text{Fix}(A^{-1}) = \{x \in X : xA^{-1} = A^{-1}\}$). Then the set $S^{-1}$ meets each coset $\text{Fix}(A)x$, $x \in X$, in a single point. It is easy to see that the family $\{Ax : x \in S^{-1}\}$ forms a subbase of the topology of $\tau$ and hence the weight of $(X, \tau)$ does not exceed $|X/\text{Fix}(A^{-1})|$. ■
Definition 9.2. A topology \( \tau \) on a group \( X \) will be called twin-generated if \( \tau \) is equal to the topology \( \tau_A \) generated by some twin subset \( A \subset X \), i.e., \( \tau \) is generated by the subbase \( \{ Ax : x \in X \} \).

Because of Theorem 8.3, we shall be especially interested in twin-generated topologies on the quasicyclic group \( C_{2\infty} \) and the infinite quaternion group \( Q_{2\infty} \). First we consider some examples.

Example 9.3. In the circle \( \mathbb{T} = \{ z \in \mathbb{C} : |z| = 1 \} \) consider the twin subset \( C_{\cap} = \{ e^{i\varphi} : 0 \leq \varphi < \pi \} \).

1. For each \( z \in \mathbb{T} \setminus C_{2\infty} \) the twin set \( C_{2\infty} \cap zC_{\cap} \) generates the Euclidean topology on \( C_{2\infty} \).
2. For each \( z \in C_{2\infty} \) the twin set \( C_{2\infty} \cap zC_{\cap} \) generates the Sorgenfrey topology on \( C_{2\infty} \).

This topology turns \( C_{2\infty} \) into a paratopological group with discontinuous inversion.

A similar situation holds for the group \( Q_{2\infty} \). Its closure in the algebra \( \mathbb{H} \) of quaternions coincides with the multiplicative subgroup \( \mathbb{T} \cup Tj \) of \( \mathbb{H} \), where \( j \in Q_8 \setminus \mathbb{C} \) is one of non-complex quaternion units.

Example 9.4. In the group \( \mathbb{T} \cup Tj \subset \mathbb{H} \) consider the twin subset \( Q_{\cap} = C_{\cap} \cup C_{\cap} j \).

1. For each \( z \in \mathbb{T} \setminus C_{2\infty} \) the twin set \( Q_{2\infty} \cap zQ_{\cap} \) generates the Euclidean topology on \( Q_{2\infty} \).
2. For each \( z \in C_{2\infty} \) the twin set \( Q_{2\infty} \cap zQ_{\cap} \) generates the Sorgenfrey topology on \( Q_{2\infty} \).

This topology turns \( Q_{2\infty} \) into a right-topological group with discontinuous inverse and discontinuous left shifts \( l_x : Q_{2\infty} \to Q_{2\infty} \) for \( x \in Q_{2\infty} \setminus C_{2\infty} \).

In the following proposition we denote by \( \tau_E \) the Euclidean topology on \( C_{2\infty} \).

Theorem 9.5. Each metrizable right-invariant topology \( \tau \supset \tau_E \) on the group \( C_{2\infty} \) (or \( Q_{2\infty} \)) is twin-generated.

Proof. First we consider the case of the group \( C_{2\infty} \). Let

\[
E_0 = C_{2\infty} \cap \{ e^{i\varphi} : -\pi/3 < \varphi < 2\pi/3 \}
\]

be the twin subset generating the Euclidean topology \( \tau_E \) on \( C_{2\infty} \) and put

\[
E_n = C_{2\infty} \cap \{ e^{i\varphi} : |\varphi| < 3^{-n-1}\pi \} \quad \text{for } n \geq 1.
\]

For every \( n \in \mathbb{N} \) let \( \varphi_n = \sum_{k=1}^{n} \pi/4^n \) and observe that \( \varphi_\infty = \sum_{k=1}^{\infty} \pi/4^n = \pi/3 \).

Let \( \tau \supset \tau_E \) be any metrizable right-invariant topology on \( C_{2\infty} \). The metrizable space \((C_{2\infty}, \tau)\) is countable and hence zero-dimensional. Since \( \tau \supset \tau_E \), there exists a neighborhood base \( \{ U_n \}_{n=1}^{\infty} \subset \tau \) at the unit 1 such that each set \( U_n \) is closed and open in \( \tau \) and \( U_n \subset E_n \) for all \( n \in \mathbb{N} \).

The interested reader can check that the twin subset

\[
A = \left( E_0 \setminus \bigcup_{n=1}^{\infty} e^{i\varphi_n} E_n \right) \cup \bigcup_{n=1}^{\infty} e^{i\varphi_n} U_n \cup \bigcup_{n=1}^{\infty} (e^{i(\pi+\varphi_n)} E_n \setminus U_n)
\]

generates the topology \( \tau \).

Next, assume that \( \tau \supset \tau_E \) is a right-invariant topology on the group \( Q_{2\infty} \). This group can be written as \( Q_{2\infty} = C_{2\infty} \cup C_{2\infty} j \), where \( j \in Q_8 \setminus \mathbb{C} \) is a non-complex quaternion.
unit. Since \( C_{2\infty} \in \tau_E \subset \tau \), the subgroup \( C_{2\infty} \) is open in \( Q_{2\infty} \). By the preceding item, the topology \( \tau \cap P(C_{2\infty}) \) on the group \( C_{2\infty} \) is generated by a twin set \( A \subset C_{2\infty} \setminus \{e^{i\varphi} : \varphi \in (2\pi/3, \pi) \cup (4\pi/3, 5\pi/3)\} \). A simple geometric argument shows that the topology \( \tau \) is generated by the twin subset \( A \cup Aj \) of \( Q_{2\infty} \). ■

**Problem 9.6.** Are all metrizable right-invariant topologies on \( C_{2\infty} \) and \( Q_{2\infty} \) twin-generated?

### 10. The characteristic group \( H(A) \) of a twin subset \( A \)

In this section, given a twin subset \( A \in T \) of a group \( X \) we introduce a twin-generated topology on the characteristic group \( H(K) \) of the 2-cogroup \( K = \text{Fix}^-(A) \).

Consider the intersection \( B = A \cap \text{Stab}(K) = B \cdot KK \) and the image \( A' = q_A(B) \) of the set \( B \) under the quotient homomorphism \( q_A : \text{Stab}(K) \to H(K) = \text{Stab}(K)/KK \). We claim that \( A' \) is a twin subset of \( H(K) \).

Indeed, for every \( x \in \text{Fix}^-(A) = K \subset \text{Stab}(K) \) we get \( X \setminus A = xA \), and consequently \( \text{Stab}(K) \setminus B = xB \) and \( H(A) \setminus A' = zA' \) where \( z \in q_A(x) \).

Now it is legal to endow the group \( H(K) \) with the topology \( \tau_{A'} \) generated by the twin subset \( A' \). This topology is generated by the subbase \( \{A'x : x \in H(K)\} \). By Proposition 9.1 the topology \( \tau_{A'} \) turns the characteristic group \( H(K) \) into a right-topological group, which will be called the **characteristic group** of \( A \) and will be denoted by \( H(A) \).

By Proposition 9.1, the characteristic group \( H(A) \) is a \( T_1 \)-space and its weight does not exceed the cardinality of \( H(A) \).

The reader should be conscious of the fact that for two twin subsets \( A, B \in T \) with \( \text{Fix}^-(A) = \text{Fix}^-(B) \) the characteristic group \( H(A) \) and \( H(B) \) are algebraically isomorphic but topologically they can be distinct: see Examples 9.3 and 9.4.

### 11. Characterizing functions that belong to \( \text{End}_X^T(F) \)

In this section for a twinic ideal \( \mathcal{I} \) on a group \( X \) and a left-invariant subfamily \( F \subset \hat{T} \) we characterize functions \( f : F \to P(X) \) that belong to the space \( \text{End}_\mathcal{I}^T(F) \). We recall that \( \text{End}_\mathcal{I}^T(F) \) is the projection of \( \text{End}_\mathcal{P}(P(X)) \) onto the face \( P(X)^F \).

**Theorem 11.1.** For a left-invariant twinic ideal \( \mathcal{I} \) on a group \( X \) and a left-invariant subfamily \( F \subset T \) a function \( \varphi : F \to P(X) \) belongs to the space \( \text{End}_\mathcal{I}^T(F) \) if and only if \( \varphi \) is equivariant, \( \mathcal{I} \)-saturated, and \( \text{Fix}^-(A) \subset \text{Fix}^-(\varphi(A)) \) for all \( A \in F \).

**Proof.** To prove the “only if” part, take any function \( \varphi \in \text{End}_\mathcal{I}^T(F) \) and find a function \( \psi \in \text{End}_\mathcal{I}^T(P(X)) \) such that \( \varphi = \psi|F \). By Theorem 4.8, the function \( \psi \) is equivariant, monotone, symmetric, and \( \mathcal{I} \)-saturated. Consequently, its restriction \( \varphi = \psi|F \) is equivariant and \( \mathcal{I} \)-saturated. Now fix any subset \( A \in F \) and take any point \( x \in \text{Fix}^-(A) \). The left-invariance of \( F \) guarantees that \( X \setminus A = xA \in F \), which means that the family \( F \) is symmetric.

Applying the equivariant symmetric function \( \psi \) to the equality \( xA = X \setminus A \), we get

\[
x \varphi(A) = x \psi(A) = \psi(xA) = \psi(X \setminus A) = X \setminus \psi(A) = X \setminus \varphi(A)
\]

and thus \( x \in \text{Fix}^-(\varphi(A)) \) and \( \text{Fix}^-(A) \subset \text{Fix}^-(\varphi(A)) \).
To prove the “if” part, fix any equivariant $\mathcal{I}$-saturated function $\varphi : F \to P(X)$ such that $\text{Fix}^{-}(A) \subset \text{Fix}^{-}(\varphi(A))$. In order to apply Theorem 4.8, we need to extend the function $\varphi$ to some symmetric $\mathcal{I}$-saturated family. This can be done as follows.

Consider the $\mathcal{I}$-saturation $\bar{\mathcal{I}} = \bigcup_{A \in F} \bar{A}/F$ of $F$. Next, extend the function $\varphi$ to the function $\bar{\varphi} : \bar{\mathcal{I}} \to F$ assigning to each set $B \in \bar{\mathcal{I}}$ the set $\varphi(A)$ where $A \in F \cap \bar{B}/F$. Since $\varphi$ is $\mathcal{I}$-saturated, the extension $\bar{\varphi}$ of $\varphi$ is well-defined and $\mathcal{I}$-saturated. The equivariance of $\varphi$ implies the equivariance of its extension $\bar{\varphi}$.

Let us check that the function $\bar{\varphi} : \bar{\mathcal{I}} \to F$ is symmetric and monotone.

To see that $\bar{\varphi}$ is symmetric, take any set $B \in \bar{\mathcal{I}}$ and find a set $A \in F \cap \bar{B}/F$. Fix any point $x \in \text{Fix}^{-}(A)$. By our hypothesis $x \in \text{Fix}^{-}(A) \subset \text{Fix}^{-}(\varphi(A))$. It follows from $A = \mathcal{I} B$ that $X \setminus A = \mathcal{I} (X \setminus B)$ and hence

$$\bar{\varphi}(X \setminus B) = \bar{\varphi}(X \setminus A) = \varphi(xA) = x \varphi(A) = X \setminus \varphi(B),$$

which means that the function $\bar{\varphi}$ is symmetric.

The monotonicity of $\bar{\varphi}$ will follow as soon as we check that $\varphi(A) = \varphi(B)$ for any sets $A, B \in F$ with $A \subset \mathcal{I} B$. Pick points $a \in \text{Fix}^{-}(A), b \in \text{Fix}^{-}(B)$. Since the ideal $\mathcal{I}$ is twinic, the chain of $\mathcal{I}$-inclusions $bB = X \setminus B \subset \mathcal{I} X \setminus A = aA \subset \mathcal{I} aB$ implies the chain of $\mathcal{I}$-equalities $bB = \mathcal{I} X \setminus B = \mathcal{I} X \setminus A = aA = \mathcal{I} aB$, which yields $A = \mathcal{I} B$ and $\varphi(A) = \varphi(B)$ as $\varphi$ is $\mathcal{I}$-saturated.

Therefore $\bar{\varphi} : \bar{\mathcal{I}} \to F$ is a left-invariant symmetric monotone $\mathcal{I}$-saturated function defined on a $\mathcal{I}$-saturated left-invariant symmetric family $\bar{\mathcal{I}}$. By Theorem 4.8, $\bar{\varphi}$ belongs to $\text{End}_{\mathcal{I}}(\bar{\mathcal{I}})$ and then its restriction $\varphi = \bar{\varphi}|F$ belongs to $\text{End}_{\mathcal{I}}(F).$

Let us recall that $\widehat{\mathcal{I}} = \{ A \subset X : \text{Fix}^{-}(A) \in \hat{K} \}$.

**Corollary 11.2.** For a left-invariant twinic ideal $\mathcal{I}$ on a group $X$ the space $\text{End}_{\mathcal{I}}(\widehat{\mathcal{I}})$ consists of all equivariant $\mathcal{I}$-saturated functions $\varphi : \widehat{\mathcal{I}} \to \widehat{\mathcal{I}}$ such that $\text{Fix}^{-}(\varphi(A)) = \text{Fix}^{-}(A)$ for all $A \in \mathcal{I}$.

A similar characterization holds for functions that belong to the space $\text{End}_{\mathcal{I}}(\mathcal{T}_K)$ for $K \in \hat{K}$ (let us observe that Theorem 4.8 is not applicable to the family $\mathcal{T}_K$ because it is not left-invariant). A function $\varphi : \mathcal{T}_K \to \mathcal{T}_K$ is $\text{Stab}(K)$-equivariant if $\varphi(xA) = x \varphi(A)$ for all $A \in \mathcal{T}_K$ and $x \in \text{Stab}(K)$.

**Proposition 13.** For any maximal $2$-cogroup $K \subset X$ and a left-invariant twinic ideal $\mathcal{I}$ on a group $X$ a function $\varphi : \mathcal{T}_K \to \mathcal{T}_K$ belongs to the space $\text{End}_{\mathcal{I}}(\mathcal{T}_K)$ if and only if $\varphi$ is $\text{Stab}(K)$-equivariant and $\mathcal{I}$-saturated.

**Proof.** The “only if” part follows from Theorem 4.8. To prove the “if part”, assume that a function $\varphi : \mathcal{T}_K \to \mathcal{T}_K$ is $\text{Stab}(K)$-invariant and $\mathcal{I}$-saturated. For any $A \in \mathcal{T}_K$ and $x \in K = \text{Fix}^{-}(A) = \text{Fix}^{-}(\varphi(A))$ we get $\varphi(X \setminus A) = \varphi(xA) = x \varphi(A) = X \setminus \varphi(A)$, which means that the function $\varphi$ is symmetric.

Now consider the families

$$\mathcal{L}_\varphi = \{ x^{-1}A : A \in F, x \in \varphi(A) \} \text{ and } \bar{\mathcal{L}}_\varphi = \bigcup_{A \in \mathcal{L}_\varphi} \bar{A}/F.$$
We claim that the family $\tilde{L}_\varphi$ is linked. Assuming the opposite, we could find two sets $A, B \in F$ and two points $x \in \varphi(A)$ and $y \in \varphi(B)$ such that $x^{-1}A \cap y^{-1}B \in \mathcal{I}$. Then $yx^{-1}A \subset \mathcal{T} X \setminus B$. Let us show that the point $c = yx^{-1}$ belongs to the subgroup $\text{Stab}(K)$ of $X$. Given any point $z \in K$, we need to prove that $c^{-1}z \in K$. Taking into account that $z \in K = \text{Fix}^{-}(B) = \text{Fix}^{-}(A)$, we see that $cA \subset \mathcal{T} X \setminus B$ implies that

$$cA \subset \mathcal{T} X \setminus B = zB \subset \mathcal{T} zc(X \setminus A) = zczA.$$ 

Since the ideal $\mathcal{I}$ is twinic, we get $cA = \mathcal{T} X \setminus B = zczA$, which implies $c^{-1}cz \in \mathcal{T} \text{Fix}(A)$. The maximality of the 2-cogroup $K = \text{Fix}^{-}(A) \subset \mathcal{T} \text{Fix}^{-}(A)$ guarantees that $\mathcal{T} \text{Fix}^{-}(A) = K$ and $\mathcal{T} \text{Fix}(A) = \mathcal{T} \text{Fix}^{-}(A) \cdot \mathcal{T} \text{Fix}^{-}(A) = KK$. Therefore $c^{-1}cz \in KK$ and $c^{-1}zc \in KKz^{-1} = K$. Now we see that $yx^{-1} = c \in \text{Stab}(K)$. So it is legitimate to apply the $\text{Stab}(K)$-invariant $\mathcal{T}$-saturated function $\varphi$ to the $\mathcal{T}$-equality $yx^{-1}A = \mathcal{T} X \setminus B$ and obtain $yx^{-1}\varphi(A) = \varphi(X \setminus B) = X \setminus \varphi(B)$. Then $x^{-1}\varphi(A) \subset X \setminus y^{-1}\varphi(B)$, which is not possible because the neutral element $e$ of the group $X$ belongs to $x^{-1}\varphi(A) \cap y^{-1}\varphi(B)$. Further we continue as in the proof of Theorem 4.8.

12. The $H(K)$-act $T_K$ of a maximal 2-cogroup $K$

In this section, given a maximal 2-cogroup $K$ in a group $X$ we study the structure of the subspace

$$T_K = \{ A \in \mathcal{P}(X) : \text{Fix}^{-}(A) = K \} \subset \mathcal{P}(X)$$

of the compact Hausdorff space $\mathcal{P}(X)$. The latter space is naturally homeomorphic to the Cantor discontinuum $2^X$ where the ordinal $2 = \{0, 1\}$ is endowed with the discrete topology.

**Proposition 12.1.** For any 2-cogroup $K \subset X$ the subspace $T_K$ of $\mathcal{P}(X)$ is homeomorphic to the Cantor discontinuum $2^{X/K^\pm}$ where $X/K^\pm = \{ K^\pm x : x \in X \}$.

**Proof.** Choose any subset $S \subset X$ that meets each coset $K^\pm x$, $x \in X$, in a single point, and consider the bijective function $\Psi : \mathcal{P}(S) \to T_K$ assigning to each subset $A \subset S$ the twin set $T_A = KKA \cup K(S \setminus A)$. Let us show that the function $\Psi$ is continuous. The subbase of the topology of $T_K$ consists of the sets $\langle x \rangle^+ = \{ B \subset T_K : x \in B \}$ and $\langle x \rangle^- = \{ B \subset T_K : x \notin B \}$, where $x \in X$. Observe that for every $z \in K$ we get $\langle z^{-1}x \rangle^+ = \{ B \subset T_K : x \in X \setminus B = zB \} = \langle z^{-1}x \rangle^+$, which means that the sets $\langle x \rangle^+$, $x \in X$, form a subbase of the topology of $T_K$.

Now the continuity of the map $\Psi$ will follow as soon as we check that for every $x \in X$ the set $\Psi^{-1}(\langle x \rangle^+) = \{ A \in \mathcal{P}(S) : x \in T_A \}$ is open in $\mathcal{P}(S)$. Fix any subset $A \in \Psi^{-1}(\langle x \rangle^+)$. Let $s$ be the unique point of the intersection $S \cap K^\pm x$. Consider the open neighborhood $O(A) = \{ A' \in \mathcal{P}(S) : A' \cap \{ s \} = A \cap \{ s \} \}$ of $A$ in the space $\mathcal{P}(S)$. We claim that $O(A) \subset \Psi^{-1}(\langle x \rangle^+)$. Fix any $A' \in O(A)$ and consider two cases:

(i) If $s \in A$, then $s \in A'$ and $x \in T_A \cap K^\pm s = KKs \subset T_{A'}$.

(ii) If $s \in S \setminus A$, then $s \in S \setminus A'$ and $x \in T_A \cap K^\pm s = Ks \subset K(S \setminus A') \subset T_{A'}$. 

In both cases $\Psi(A') = T_{A'} \in \langle x \rangle^+$. Now we see that $\Psi : P(S) \to T_K$, being a continuous bijective map defined on the compact Hausdorff space $P(S)$, is a homeomorphism. It remains to observe that $P(S)$ is homeomorphic to $2^{X/K}$.

Let us observe that in general the subfamily $T_K \subset P(X)$ is not left-invariant. Indeed, for any $A \in T_K$ and $x \in X$ the shift $xA$ belongs to $T_K$ if and only if $K = \text{Fix}^-(xA) = x\text{Fix}^-(A) x^{-1} = xK x^{-1}$ if and only if $x \in \text{Stab}(K)$. Thus the family $T_K$ can be considered as an act endowed with the left action of the group $\text{Stab}(K)$.

For any twin set $A \in T_K$ its stabilizer $\text{Fix}(A) = \{x \in X : xA = A\}$ is equal to $\text{Fix}^-(A) \cdot \text{Fix}^-(A) = KK$ and hence is a normal subgroup of $\text{Stab}(K)$. This implies that the characteristic group $H(K) = \text{Stab}(K)/KK$ acts freely on the space $T_K$. Therefore, we can (and will) consider the space $T_K$ as a free $H(K)$-act. For each set $A \in T_K$ we denote by

$$[A] = \{xA : x \in \text{Stab}(K)\} = \{hA : h \in H(K)\}$$

the orbit of $A$ in $T_K$ and by $[T_K] = \{[A] : A \in T_K\}$ the orbit space of the $H(K)$-act $T_K$, endowed with the quotient topology. By Theorem 3.1 the $H(K)$-act $T_K$ is isomorphic to $[T_K] \times H(K)$. In some cases the isomorphism between the $H(K)$-acts $T_K$ and $[T_K] \times H(K)$ is topological.

**Proposition 12.2.** The orbit space $[T_K]$ is a $T_1$-space if and only if the characteristic group $H(K)$ is finite. In this case $[T_K]$ is a compact Hausdorff space and the orbit map $q : T_K \to [T_K]$ has a continuous section $s : [T_K] \to T_K$, which implies that $T_K$ is homeomorphic to the product $[T_K] \times H(K)$ where the (finite) group $H(K)$ is endowed with the discrete topology.

**Proof.** By Theorem 8.3 the characteristic group $H(K)$ is at most countable. Since $T_K$ is a free $H(K)$-act, each orbit $[A]$, $A \in T_K$, has cardinality $|\{A\}| = |H(K)|$ and hence is at most countable. Note that the orbit $[A]$ admits a transitive action of the group $H(K)$ and hence is topologically homogeneous.

If $[T_K]$ is a $T_1$-space, then each orbit $[A]$, $A \in T_K$, is closed in the compact Hausdorff space $T_K$. Now the Baire theorem implies that $[A]$ has an isolated point and is discrete (being topologically homogeneous). Taking into account that $[A]$ is compact and discrete, we conclude that it is finite. Consequently, $|H(K)| = |\{A\}| < \aleph_0$.

Now assume that the characteristic group $H(K)$ is finite. Let $q : T_K \to [T_K]$ denote the orbit map. To show that the orbit space $[T_K]$ is Hausdorff, pick two distinct orbits $[A]$ and $[B]$. Since $H(K)$ is finite and $xA \neq yB$ for any $x, y \in H(K)$, we can find two neighborhoods $O(A)$ and $O(B)$ of $A, B$ in $T_K$ such that $xO(A) \cap yO(B) = \emptyset$ for all $x, y \in H(K)$. Then $O([A]) = \bigcup_{x \in H(K)} xO(A)$ and $O([B]) = \bigcup_{y \in H(K)} yO(B)$ are two disjoint open $H(K)$-invariant subsets in $T_K$. Their images $q(O([A]))$ and $q(O([B]))$ are disjoint open neighborhoods of $[A]$, $[B]$ in $[T_K]$, which means that the orbit space $[T_K]$ is Hausdorff. This space is compact and zero-dimensional as the image of the compact zero-dimensional space $T_K$ under the open continuous map $q : T_K \to [T_K]$.

Using the zero-dimensionality of $[T_K]$ and the finiteness of $H(K)$ it is easy to construct a continuous section $s : [T_K] \to T_K$ of the map $q$ and prove that $T_K$ is homeomorphic to $H(K) \times [T_K]$. ■
Let us recall that a subfamily $F \subset P(X)$ is $\lambda$-invariant if $f(F) \subset F$ for any equivariant symmetric monotone function $f : P(X) \to P(X)$. For a $\lambda$-invariant subfamily $F \subset P(X)$ the projection

$$\text{End}_\lambda(F) = \{ f | F : f \in \text{End}_\lambda(P(X)) \}$$

is a subsemigroup of the semigroup $F^F$ of all self-mappings of $F$.

**Proposition 12.3.** For any maximal $2$-cogroup $K \subset X$ the family $T_K$ is $\lambda$-invariant and hence $\text{End}_\lambda(T_K)$ is a compact right-topological semigroup.

**Proof.** Given any function $f \in \text{End}_\lambda(P(X))$ and a set $A \in T_K$ we need to show that $f(A) \in T_K$. By Corollary 4.4 the function $f$ is equivariant and symmetric. Then for any $x \in K = \text{Fix}^{-}(A)$ we get $xA = X \setminus A$ and hence $x\varphi(A) = \varphi(xA) = \varphi(X \setminus A) = X \setminus \varphi(A)$, which means that $x \in \text{Fix}^{-}(\varphi(A))$ and $K \subset \text{Fix}^{-}(\varphi(A))$. The maximality of the $2$-cogroup $K$ guarantees that $K = \text{Fix}^{-}(\varphi(A))$ and thus $\varphi(A) \in T_K$. So, the family $T_K$ is $\lambda$-invariant. □

### 13. $\mathcal{I}$-incomparable and $\mathcal{I}$-independent families

Let $\mathcal{I}$ be a left-invariant ideal on a group $X$. A family $F \subset P(X)$ is called

- $\mathcal{I}$-incomparable if $\forall A, B \in F \ (A \subset_\mathcal{I} B \Rightarrow A =_\mathcal{I} B)$;
- $\mathcal{I}$-independent if $\forall A, B \in F \ (A =_\mathcal{I} B \Rightarrow A = B)$.

**Proposition 13.1.** A left-invariant ideal $\mathcal{I}$ on a group $X$ is twinic if and only if the family $pT^\mathcal{I}$ of $\mathcal{I}$-pretwin sets is $\mathcal{I}$-incomparable.

**Proof.** First assume that the family $pT^\mathcal{I}$ is $\mathcal{I}$-incomparable. To show that the ideal $\mathcal{I}$ is twinic, take any subset $A \subset X$ with $xA \subset_\mathcal{I} X \setminus A \subset_\mathcal{I} yA$ for some $x, y \in X$. Then $A \in pT^\mathcal{I}$ and also $xA, yA \in pT^\mathcal{I}$. Since $xA \subset_\mathcal{I} yA$, the $\mathcal{I}$-incomparability of the family $pT^\mathcal{I}$ implies that $xA =_\mathcal{I} yA$ and then $xA =_\mathcal{I} X \setminus A =_\mathcal{I} yA$, which means that the ideal $\mathcal{I}$ is twinic.

Now assume conversely that $\mathcal{I}$ is twinic and take two $\mathcal{I}$-pretwin sets $A \subset_\mathcal{I} B$. Since the sets $A, B$ are $\mathcal{I}$-pretwin, there are elements $x, y \in X$ such that $xB \subset_\mathcal{I} X \setminus B$ and $X \setminus A \subset_\mathcal{I} yA$. Taking into account that

$$xB \subset_\mathcal{I} X \setminus B \subset_\mathcal{I} X \setminus A \subset_\mathcal{I} yA \subset_\mathcal{I} yB,$$

and $\mathcal{I}$ is twinic, we conclude that $X \setminus B =_\mathcal{I} X \setminus A$ and hence $A =_\mathcal{I} B$. □

**Corollary 13.2.** For each twinic left-invariant ideal $\mathcal{I}$ on a group $X$ the family $T$ of twin sets is $\mathcal{I}$-incomparable.

**Proposition 13.3.** For a left-invariant ideal $\mathcal{I}$ on a group $X$ the family $\hat{T}$ is $\mathcal{I}$-independent if and only if $\mathcal{I} \cap \hat{K} = \emptyset$.

**Proof.** To prove the “only if” part, assume that the ideal $\mathcal{I}$ contains some maximal $2$-cogroup $K \in \hat{K}$. Since $\mathcal{I}$ is left-invariant, for each $x \in K$, $KK = xK \in \mathcal{I}$ and hence $K^\pm = K \cup KK \in \mathcal{I}$. 

Choose a subset \( S \subset X \) that contains the neutral element \( e \) of the group \( X \) and meets each coset \( K^\pm x, x \in X \), in a single point. Then \( A = KK_S \) and \( B = KK(S \setminus \{e\}) \cup K \) are two distinct twin sets with \( K \subset \text{Fix}^-(A) \cap \text{Fix}^-(B) \). By the maximality of \( K, K = \text{Fix}^-(A) = \text{Fix}^-(B) \) and hence \( A, B \in \tilde{T} \). Since the symmetric difference \( A \triangle B = KK \cup K = K^\pm \) is in \( \mathcal{I} \), we get \( A =_\mathcal{I} B \), which means that the family \( \tilde{T} \) fails to be \( \mathcal{I} \)-independent.

To prove the “if” part, assume that the family \( \tilde{T} \) is not \( \mathcal{I} \)-independent and find two subsets \( A, B \in \tilde{T} \) such that \( A \neq B \) but \( A =_\mathcal{I} B \). The 2-cogroup \( \text{Fix}^-(A) \) of \( A \) is maximal and hence coincides with the 2-cogroup \( \mathcal{I} \cdot \text{Fix}^-(A) \supset \text{Fix}^-(A) \). For the same reason, \( \text{Fix}^-(B) = \mathcal{I} \cdot \text{Fix}^-(B) \). The \( \mathcal{I} \)-equality \( A =_\mathcal{I} B \) implies \( \mathcal{I} \cdot \text{Fix}^-(A) = \mathcal{I} \cdot \text{Fix}^-(B) \). Denote the maximal 2-cogroup \( \text{Fix}^-(A) = \mathcal{I} \cdot \text{Fix}^-(A) = \mathcal{I} \cdot \text{Fix}^-(B) = \text{Fix}^-(B) \) by \( K \). Then \( \text{Fix}(A) = \text{Fix}^-(A) \cdot \text{Fix}^-(A) = KK = \text{Fix}(B) \) and hence \( A = KKA \) and \( B = KKB \).

Now we see that the symmetric difference \( A \triangle B = KKA \cup KKB \) contains a subset \( KKx \) for some \( x \in X \). Then for any \( y \in K \), we get \( Kyx = KKx \subset A \triangle B \in \mathcal{I} \) and hence \( Kyx \in \mathcal{I} \). Finally observe that the set \( K'y = x^{-1}y^{-1}Ky \) is a maximal 2-cogroup and by the left-invariance of the ideal \( \mathcal{I} \), \( K'y = x^{-1}y^{-1}Ky = Kx \in \mathcal{I} \). So, \( \hat{K} \cap \mathcal{I} \neq \emptyset \).

**Proposition 13.4.** A subfamily \( F \subset \mathcal{P}(X) \) is \( \mathcal{I} \)-independent for any left-invariant ideal \( \mathcal{I} \) on \( X \) if for each set \( A \in F \) the subgroup \( \text{Fix}(A) \) has finite index in \( X \).

**Proof.** Assume that \( A, B \in F \) are two subsets with \( A =_\mathcal{I} B \) for some left-invariant ideal \( \mathcal{I} \). Since the subgroups \( \text{Fix}(A) \) and \( \text{Fix}(B) \) have finite indices in \( X \), their intersection \( \text{Fix}(A) \cap \text{Fix}(B) \) also has finite index in \( X \) and contains a normal subgroup \( H \subset X \) of finite index in \( X \) (see [14] I.Ex.9(a)]. Then \( X = FH \) for some finite subset \( F \subset X \). Assuming that \( A \neq B \), we can find a point \( x \in A \triangle B \) and conclude that \( xH = Hx \subset H A \triangle H B = A \triangle B \in \mathcal{I} \) and \( X = FH \in \mathcal{I} \) by the left-invariance of the ideal \( \mathcal{I} \). This contradiction completes the proof.

**Proposition 13.5.** Each minimal \( \hat{K} \)-covering subfamily \( \tilde{T} \subset \tilde{T} \) is \( \mathcal{I} \)-independent.

**Proof.** Fix any two sets \( A, B \in \tilde{T} \) with \( A =_\mathcal{I} B \). Repeating the argument from the proof of Proposition 13.3 we can prove that \( \mathcal{I} \cdot \text{Fix}^-(A) = \text{Fix}^-(A) = \mathcal{I} \cdot \text{Fix}^-(B) = \text{Fix}^-(B) = K \) for some maximal 2-cogroup \( K \in \hat{K} \). Since the family \( \tilde{T} \ni A, B \) is minimal \( \hat{K} \)-covering, the sets \( A, B \) lie in the same orbit and hence \( A =xB \) for some \( x \in X \). It follows from \( B =_\mathcal{I} A =x B \) that \( x \in \mathcal{I} \cdot \text{Fix}(B) = \text{Fix}(B) \) and thus \( A =xB = B \).

### 14. The endomorphism monoid \( \text{End}(T_K) \) of the \( H(K) \)-act \( T_K \)

For any maximal 2-cogroup \( K \) in a group \( X \) the compact right-topological semigroup \( \text{End}_\lambda(T_K) \) is a subsemigroup of the endomorphism monoid \( \text{End}(T_K) \) of the free \( H(K) \)-act \( T_K \). The endomorphism monoid \( \text{End}(T_K) \) is the space of all (not necessarily continuous) functions \( f : T_K \to T_K \) that are equivariant in the sense that \( f(xA) = xf(A) \) for all \( A \in T_K \) and \( x \in \text{Stab}(K) \). It is easy to check that \( \text{End}(T_K) \) is a closed subsemigroup of the compact Hausdorff right-topological semigroup \( T_K^{s^*} \) of all self-maps of the compact
Hausdorff space $T_K$. So, $\text{End}(T_K)$ is a compact Hausdorff right-topological semigroup that contains $\text{End}_\lambda(T_K)$ as a closed subsemigroup.

If $\mathcal{I}$ is a left-invariant ideal on the group $X$, then the left ideal $\text{End}_\lambda^\mathcal{I}(T_K)$ of $\text{End}_\lambda(T_K)$ lies in the left ideal $\text{End}_\lambda^\mathcal{I}(T_K) \subset \text{End}(T_K)$ consisting of all equivariant functions $f : T_K \to T_K$ which are $\mathcal{I}$-saturated in the sense that $f(A) = f(B)$ for all $A, B \in T_K$ with $A =_\mathcal{I} B$.

In the following theorem we describe some algebraic and topological properties of the endomorphism monoid $\text{End}(T_K)$.

**Theorem 14.1.** Let $K$ be a maximal 2-cogroup in a group $X$. Then:

1. $\text{End}_\lambda^\mathcal{I}(T_K) = \text{End}_\lambda(T_K) \subset \text{End}_\lambda(T_K) \subset \text{End}(T_K)$ for any twinic ideal $\mathcal{I}$ on $X$;
2. $\text{End}_\lambda^\mathcal{I}(T_K) = \text{End}(T_K)$ for any left-invariant ideal $\mathcal{I}$ on $X$ such that $\mathcal{I} \cap \hat{K} = \emptyset$;
3. the semigroup $\text{End}(T_K)$ is algebraically isomorphic to the wreath product $H(K) \wr [T_K]$;
4. for each idempotent $f \in \text{End}(T_K)$ the maximal subgroup $H_f \subset \text{End}(T_K)$ containing $f$ is isomorphic to $H(K) \wr [f(T_K)]$;
5. the minimal ideal $K(\text{End}(T_K)) = \{ f \in \text{End}(T_K) : \forall A \in f(T_K), f(T_K) \subset [A] \}$;
6. each minimal left ideal of the semigroup $\text{End}(T_K)$ is algebraically isomorphic to $H(K) \times [T_K]$ where the orbit space $[T_K]$ is endowed with the left zero multiplication;
7. each maximal subgroup of the minimal ideal $K(\text{End}(T_K))$ is algebraically isomorphic to $H(K)$;
8. each minimal left ideal of the semigroup $\text{End}(T_K)$ is homeomorphic to $T_K$;
9. for each minimal idempotent $f \in K(\text{End}(T_K))$ the maximal subgroup $H_f = f \circ \text{End}(T_K) \circ f$ is topologically isomorphic to the twin-generated group $H(A)$ where $A \in f(T_K)$.

**Proof.** 1, 2. The first statement follows from Proposition 11.3 and the second one from Proposition 13.3.

3–7. Since $T_K$ is a free $H(K)$-act, the (algebraic) statements (3)–(7) follow from Theorem 3.1.

8. Given a minimal idempotent $f \in \text{End}(T_K)$, we need to prove that the minimal left ideal $L_f = \text{End}(T_K) \circ f$ is homeomorphic to $T_K \subset P(X)$. For this fix any set $B \in f(T_K)$ and observe that $f(T_K) \subset [B]$ according to the statement (5). We claim that the map

$$\Psi : L_f \to T_K, \quad \Psi : g \mapsto g(B),$$

is a homeomorphism. The definition of the topology (of pointwise convergence) on $\text{End}(T_K)$ implies that the map $\Psi$ is continuous.

Next, we show that the map $\Psi$ is bijective. To show that $\Psi$ is injective, fix any two distinct functions $g, h \in L_f$ and find a set $A \in T_K$ such that $g(A) \neq h(A)$. Since $f(T_K) \subset [B]$, there is $x \in X$ such that $f(A) = xB$. Then

$$xg(B) = g(xB) = gf(A) = g(A) \neq h(A) = hf(A) = h(xB) = xh(B)$$

and hence $\Psi(g) = g(B) \neq h(B) = \Psi(h)$. To show that $\Psi$ is surjective, take any subset $C \subset T_K$ and choose any equivariant map $\varphi : [B] \to [C]$ such that $\varphi(B) = C$. Then the function $g = \varphi \circ f$ belongs to $L_f$ and has image $\Psi(g) = g(B) = C$, witnessing
that $\Psi$ is surjective. Since $L_f$ is compact, the bijective continuous map $\Psi : L_f \to T_K$ is a homeomorphism. By Proposition 12.1, the space $T_K$ is homeomorphic to the cube $2^X/K^\pm$.

9. Given a minimal idempotent $f \in \text{End}(T_K)$ we shall show that the maximal subgroup $H_f = f \circ \text{End}(T_K) \circ f$ is topologically isomorphic to the characteristic group $H(A)$ of any twin set $A \in f(T_K)$.

We recall that $H(A)$ is the characteristic group $H(K)$ of the 2-cogroup $K = \text{Fix}^-(A)$, endowed with the topology generated by the twin set $q(A \cap \text{Stab}(K))$ where $q : \text{Stab}(K) \to H(K) = \text{Stab}(K)/K K$ is the quotient homomorphism.

We define a topological isomorphism $\Theta_A : H_f \to H(A)$ in the following way. Since $f$ is a minimal idempotent, $g(A) = fgf(A) \in f(T_K) \subset [A]$. So we can find $x \in \text{Stab}(K)$ with $fgf(A) = x^{-1}A$. Now define $\Theta_A(g)$ as the image $q(x) = xK K x = K K x$ of $x$ under the quotient homomorphism $q : \text{Stab}(K) \to H(K) = H(A)$.

It remains to prove that $\Theta_A : H_f \to H(A)$ is a well-defined topological isomorphism of right-topological groups.

First we check that $\Theta_A$ is well-defined, that is, $\Theta_A(g) = q(x)$ does not depend on the choice of the point $x$. Indeed, for any other point $y \in X$ with $g(A) = y^{-1}A$ we get $x^{-1}A = y^{-1}A$ and thus $yx^{-1} \in \text{Fix}(A) = K \cdot K$ where $K = \text{Fix}^-(A)$. Consequently, $q(x) = K K x = K K y = q(y)$.

Next, we prove that $\Theta_A$ is a group homomorphism. Given two functions $g, h \in H_f$, find elements $x_g, x_h \in \text{Fix}(A)$ such that $h(A) = x_h^{-1}A$ and $g(A) = x_g^{-1}A$. It follows that $g \circ h(A) = g(x_h^{-1}A) = x_h^{-1}g(A) = x_h^{-1}x_g^{-1}A = (x_gx_h)^{-1}A$, which implies that $\Theta_A(g \circ h) = x_gx_h K K = \Theta_A(g) \cdot \Theta_A(h)$.

Now, we calculate the kernel of the homomorphism $\Theta_A$. Take any function $g \in H_f$ with $\Theta_A(g) = e$, which means that $g(A) = fgf(A) = A$. Then for every $A' \in T_K$ we can find $x \in X$ with $f(A') = xA$ and conclude that $g(A') = fgf(A') = f(xA) = xfg(A) = xfgf(A) = xA = f(A')$, witnessing that $g = fgf = f$. This means that the homomorphism $\Theta_A$ is one-to-one.

To see that $\Theta_A$ is onto, first observe that each element of the characteristic group $H(A)$ can be written as $[y] = yKKy \in H(K)$ for some $y \in \text{Stab}(K)$. Given such an element $[y] \in H(A)$, consider the equivariant function $s_{[y]} : [A] \to [A]$, $s_{[y]} : zA \mapsto zy^{-1}A = zy^{-1}KKA$. Let us show that this function is well-defined. Indeed, for each point $u \in X$ with $zA = uA$, we get $u^{-1}z \in \text{Fix}(A)$ and hence $yu^{-1}zy^{-1} \in y\text{Fix}(A)y^{-1} = yKKy^{-1} = KK = \text{Fix}(A)$. Then $yu^{-1}zy^{-1}A = A$ and hence $zy^{-1}A = uy^{-1}A$.

It follows from $s_{[y]} \circ f = f \circ s_{[y]} \circ f$ that the function $s_{[y]} \circ f$ belongs to the maximal group $H_f$. Since $s_{[y]} \circ f(A) = s_{[y]}(A) = y^{-1}A$, the image $\Theta_A(s_{[y]} \circ f) = [y]$. So, $\Theta_A(H_f) = H(A)$ and $\Theta_A : H_f \to H(A)$ is an algebraic isomorphism.

It remains to prove that this isomorphism is topological. Observe that for every $[y] \in H(A)$ we get $s_{[y]} \circ f(A) = s_{[y]}(A) = y^{-1}KKA = y^{-1}A$. Consequently, $x \in s_{[y]} \circ f(A)$ iff $x \in y^{-1}A$ iff $y \in Ax^{-1}$.

To see that the map $\Theta_A : H_f \to H(A)$ is continuous, take any subbasic open set

$$U_x = \{[y] \in H(A) : y \in Ax^{-1}\}, \quad x \in \text{Stab}(K),$$

in $H(A)$ and observe that $\Theta_A^{-1}(U_x) = \{s_{[y]} \circ f : [y] \in U_x \} = \{s_{[y]} \circ f : y \in Ax^{-1}\} = \{yK K y^{-1} : y \in Ax^{-1}\}\cap H(A)$. Since $\Theta_A$ is continuous, the function $\Theta_A^{-1}$ is open and hence we obtain $\Theta_A^{-1}(U_x)$ as the open set $\{yK K y^{-1} : y \in Ax^{-1}\}$ in $H(A)$. Therefore, $\Theta_A$ is continuous.
\{s[y] \circ f : x \in s[y] \circ f(A)\} is a subbasic open set in \(H(f)\). To see that the inverse map 
\(\Theta_A^{-1} : H(A) \to H_f\) is continuous, take any subbasic open set \(V_{x,T} = \{g \in H(f) : x \in g(T)\}\) where \(x \in X\) and \(T \in T_K\). It follows that \(f(T) = x_T A\) for some \(x_T \in X\). Then
\[
\Theta_A(V_{x,T}) = \{[y] \in H(A) : x \in s[y] \circ f(T)\} = \{[y] \in H(A) : x \in s[y](x_T A)\} = \{[y] \in H(A) : x_T^{-1} x \in s[y](A)\} = \{[y] \in H(A) : y \in Ax^{-1} x_T\}
\]
is a subbasic open set in \(H(A)\).

In the following proposition we calculate the cardinalities of the objects appearing in
Theorem \[14.1\] We shall say that a cardinal \(k \geq 1\) divides a cardinal \(m \geq 1\) if there is a
 cardinal \(k\) such that \(m = k \times n\). The smallest such \(k\) is denoted by \(m/n\).

**Proposition 14.2.** If \(K \in \mathcal{K}\) is a maximal 2-cogroup in a group \(X\), then

1. \(|T_K| = 2^{\lfloor X/K\}^\pm \rfloor\);
2. \(|H(K)| \in \{2^k : k \in \mathbb{N}\} \cup \{\aleph_0\}\) and \(|H(K)|\) divides the index \(|X/K|\) of \(K\) in \(X\);
3. \(|T_K| = |H(K)| \divides X/KK\) divides \(|X/KK| = |X/K|\);
4. \(|H(K)| = |X/K|\) if the 2-cogroup \(K\) is normal in \(X\).

**Proof.** Choose any subset \(S \subset X\) that meets each coset \(K^\pm x, x \in X\), of the group
\(K^\pm = K \cup KK\) in a single point. It is clear that \(|S| = |X/K^\pm|\).

1. The equality \(|T_K| = 2^{\lfloor X/K\}^\pm \rfloor\) follows from Proposition \[12.1\]

2. By Theorem \[8.3\] \(|H(K)| \in \{2^n : n \in \mathbb{N}\} \cup \{\aleph_0\}\). Since \(\text{Stab}(K)\) is a subgroup of \(X\),
\(|H(K)| = |\text{Stab}(K)/KK|\) divides \(|X/KK| = |X/K|\).

3. Since \(T_K\) is a free \(H(K)\)-act, \(|T_K| = |T_K|/|H(K)|\). This equality is clear if \(H(K)\)
is finite. If \(H(K)\) is infinite, then \(|H(K)| = \aleph_0\) and the index \(|X/K^\pm|\) of the group \(K^\pm\)
in \(X\) is infinite. In this case \(|T_K| = 2^{\lfloor X/K\}^\pm \rfloor > \aleph_0\) and thus \(|T_K| = 2^{\lfloor X/K\}^\pm \rfloor/\aleph_0 = 2^{\lfloor X/K\}^\pm \rfloor\).

4. If the \(2\)-cogroup \(K\) is normal in \(X\), then \(\text{Stab}(K) = X\) and \(H(K) = X/KK\). In
this case \(|H(K)| = |X/KK| = |X/K|\).

By Theorem \[14.1\](6), for any maximal \(2\)-cogroup \(K \subset X\) each minimal left ideal of the
semigroup \(\text{End}(T_K)\) is algebraically isomorphic to \(H(K) \times |T_K|\). It turns out that in some
cases this isomorphism is topological. We recall that the orbit space \(|T_K| = T_K/H(K)\) is endowed with the quotient topology. By Proposition \[12.2\] the orbit space \(|T_K|\) is compact and Hausdorff if and only if the characteristic group \(H(K)\) is finite.

Since \(T_K\) is a compact Hausdorff space, the Tikhonov power \(T_K^T\) is a compact Hausdorff right topological semigroup (endowed with the operation of composition of functions). This semigroup contains the subsemigroup \(C(T_K, T_K)\) consisting of all continuous maps \(f : T_K \to T_K\). It is easy to check that the semigroup \(C(T_K, T_K)\) is semitopological.

We recall that a right-topological semigroup \(S\) is called semitopological if the semigroup operation \(S \times S \to S\) is separately continuous. If the semigroup operation is continuous, then \(S\) is called a topological semigroup.

**Theorem 14.3.** Let \(K\) be a maximal \(2\)-cogroup in a group \(X\). For a minimal idempotent \(f\) in the semigroup \(\text{End}(T_K)\) and its minimal left ideal \(L_f = \text{End}(T_K) \circ f\) the following conditions are equivalent:
(1) \( L_f \) is a topological semigroup;
(2) \( L_f \) is topologically isomorphic to the topological semigroup \( [T_K] \times H(K) \) where the orbit space \([T_K]\) is endowed with the left zero multiplication;
(3) \( L_f \) is a semitopological semigroup;
(4) the left shift \( l_f: L_f \to L_f, \; l_f : g \mapsto f \circ g, \) is continuous;
(5) \( f \) is continuous;
(6) \( L_f \subset C(T_K, T_K) \);
(7) \( H(K) \) is finite and the idempotent band \( E(L_f) \) of \( L_f \) is compact.

Proof. The implications (2)\(\Rightarrow\)(1)\(\Rightarrow\)(3)\(\Rightarrow\)(4) are trivial.

(4)\(\Rightarrow\)(5) Assume that the left shift \( l_f: L_f \to L_f \) is continuous. We need to check that \( f \) is continuous. First we show that for any set \( B \in f(T_K) \) the preimage \( Z = f^{-1}(B) \) is closed in \( T_K \). Assume that \( f^{-1}(B) \) is not closed and find a point \( A_0 \in \mathbb{Z} \setminus Z \). It follows that the set \( B_0 = f(A_0) \) is not equal to \( B \). Let \( \varphi: [B] \to [A_0] \) be a unique equivariant function such that \( \varphi(B) = A_0 \). Then the function \( g_0 = \varphi \circ f \) belongs to the minimal left ideal \( L_f \). Observe that \( f \circ g_0(B) = f(A_0) = B_0 \neq B \). Since the left shift \( l_f \) is continuous, for the neighborhood \( O(f \circ g_0) = \{ h \in L_f : h(B) \neq B \} \) of \( f \circ g_0 = l_f(g_0) \) there is a neighborhood \( O(g_0) \subset L_f \) such that \( f \circ g \subset O(f \circ g_0) \) for every \( g \in O(g_0) \). It follows from the equivalence of \( g_0 = g \circ f \) and the definition of the topology (of pointwise convergence) on \( L_f \subset T_K^\infty \) that the point \( g_0(B) = A_0 \) of \( T_K \) has a neighborhood \( O(A_0) \subset T_K \) such that each function \( g \in L_f \) with \( g(B) \in O(A_0) \) belongs to the neighborhood \( O(g_0) \). Since \( A_0 \) is a limit point of the set \( Z \), there is a set \( A \in O(A_0) \cap Z \). For this set find an equivariant function \( g = g \circ f \) such that \( g(B) = A \). Then \( g \in O(g_0) \) and hence \( f \circ g(B) \neq B \), which contradicts \( g(B) = A \in f^{-1}(B) \). This contradiction proves that all preimages \( f^{-1}(B), \; B \in f(T_K), \) are closed in \( T_K \).

Next, we show that each orbit \([A], \; A \in T_K, \) is discrete. Assume that some orbit \([A]\) is not discrete and consider its closure \( \overline{[A]} \) in the compact Hausdorff space \( T_K \). The orbit \([A]\) has no isolated points, being non-discrete and topologically homogeneous. Fix any \( B \in f(T_K) \). By Theorems 3.12 and 8.3 \( |f(T_K)| = |[B]| = |H(K)| \leq \aleph_0 \). Thus we can write the compact space \( [A] \) as a countable union

\[
[A] = \bigcup_{B \in f(T_K)} f^{-1}(B) \cap [A]
\]

of closed subsets. By Baire’s Theorem, for some \( B \in f(T_K) \) the set \( \overline{[A]} \cap f^{-1}(B) \) has non-empty interior in \( \overline{[A]} \). Since the orbit \([A]\) has no isolated points, the intersection \( [A] \cap f^{-1}(B) \) is infinite, which is not possible as \( f \) is equivariant.

Finally, we show that for every \( B \in f(T_K) \) the preimage \( f^{-1}(B) \) is open in \( L_f \). Assuming the opposite, we can find a point \( A_0 \in f^{-1}(B) \) that lies in the closure of the set \( T_K \setminus f^{-1}(B) \). Choose any equivariant function \( g_0 \in L_f \) such that \( g_0(B) = A_0 \) and observe that \( f \circ g_0(B) = B \).

Since the orbit \([B]\) of \( B \) is discrete, we can find an open neighborhood \( O(B) \subset T_K \) of \( B \) such that \( O(B) \cap [B] = \{B\} \). This neighborhood determines a neighborhood \( O(f \circ g_0) = \{ g \in L_f : g(B) \in O(B) \} \) of the function \( f \circ g_0 \) in \( L_f \subset T_K^\infty \). Since the left shift \( l_f : L_f \to L_f \) is continuous, the function \( g_0 \) has a neighborhood \( O(g_0) \subset L_f \) such
that $l_f(O(g_0)) \subset O(f \circ g_0)$. By the definition of the topology (of pointwise convergence) on $L_f$, there is a neighborhood $O(g_0(B)) \subset T_K$ such that each function $g \in L_f$ with $g(B) \in O(g_0(B))$ belongs to $O(g_0)$. By the choice of the point $A_0 = g_0(B)$, there is a set $A \in O(g_0(B)) \setminus f^{-1}(B)$. For this set choose an equivariant function $g \in L_f$ such that $g(B) = A$. This function $g$ belongs to $O(g_0)$ and thus $f \circ g \in O(f \circ g_0)$, which means that $f \circ g(B) = B$. But this contradicts $g(B) \notin f^{-1}(B)$.

Thus for each $B \in f(T_K)$ the preimage $f^{-1}(B)$ is open in $T_K$, which implies that the function $f : T_K \rightarrow T_K$ is continuous.

$(5) \Rightarrow (6)$ Assume that $f$ is continuous. Then for any $B \in T_K$ the orbit $|B| = f(T_K)$ is compact (as a continuous image of the compact space $T_K$). Being a compact topologically homogeneous space of cardinality $|B| \leq |H(K)| \leq \aleph_0$, the orbit $|B| = f(T_K)$ is finite. Then for each $g \in L_f$ the restriction $g|B|$ is continuous and hence $g = g \circ f$ is continuous as the composition of two continuous maps $f$ and $g|B|).

$(6) \Rightarrow (7)$ Assume that $L_f \subset C(T_K, T_K)$. Then $f$ is continuous. Repeating the argument from the preceding item, we can show that the characteristic group $H(K)$ is finite. By the continuity of $f$, for every $B \in T_K$ the preimage $f^{-1}(B)$ is closed in $T_K$. In the following claim $E(L_f)$ stands for the idempotent band of the semigroup $L_f$.

**Claim 14.4.** $E(L_f) = \{g \in L_f : f \circ g(B) = B\}$.

**Proof.** If $g \in L_f$ is an idempotent, then for the unique point $C \in g(T_K) \cap f^{-1}(B)$ we get $C = g(C)$ and then $B = f(C) = fg(C) = fgf(C) = fg(B)$.

Now assume conversely that $g \in L_f$ with $fg(B) = B$. Let $C = g(B) \in g(T_K)$. Then $g(C) = gf(C) = gfg(B) = g(B) = C$. For every $A \in T_K$ we can find $x \in X$ such that $g(A) = xC$ and so $gg(A) = g(xC) = xg(C) = xC = g(A)$, which means that $g$ is an idempotent.

Since the set $f^{-1}(B) \subset T_K$ is closed and the evaluation map

$$c_B : L_f \rightarrow T_K, \quad c_B : g \mapsto g(B),$$

is continuous, the preimage $c_B^{-1}(f^{-1}(B))$ is closed in $L_f$. By Claim 14.4, this preimage is equal to the idempotent band $E(L_f)$ of the semigroup $L_f$.

$(7) \Rightarrow (2)$ Assume that the group $H(K)$ is finite and the idempotent band $E(L_f)$ is compact. By Proposition 12.2, the orbit space $[T_K]$ is compact, Hausdorff and zero-dimensional, and the quotient map $q : T_K \rightarrow [T_K]$ is continuous and open.

We claim that for every $B \in f(T_K)$ the preimage $f^{-1}(B) \subset T_K$ is compact. Since the idempotent band $E(L_f)$ is compact and the evaluation map $c_B : L_f \rightarrow T_K, c_B : g \mapsto g(B)$, is continuous, the image $c_B(E(L_f))$ is compact. By Claim 14.4, $c_B(E(L_f)) \subset f^{-1}(B)$. To show the reverse inclusion, fix any subset $A \in f^{-1}(B)$ and choose any equivariant map $\varphi : [B] \rightarrow [A]$ such that $\varphi(B) = A$. Then the map $g = \varphi \circ f$ belongs to $L_f$ and is an idempotent by Claim 14.4. Since $A = g(B)$, we see that $f^{-1}(B) \subset c_B(E(L_f))$ and hence $f^{-1}(B) = c_B(E(L_f))$ is compact.

Fix any set $B \in f(T_K)$. Since $|f(T_K)| = |[B]| = |H(K)| < \aleph_0$, the preimage

$$Z = f^{-1}(B) = T_K \setminus \bigcup_{B \neq A \in [B]} f^{-1}(A)$$

is a subset of $T_K$.
is open-and-closed in $T_K$. Since the compact space $Z$ meets each orbit $[A]$, $A \in T_K$, in a single point, the restriction $q|Z : Z \to [T_K]$, being continuous and bijective, is a homeomorphism. So, it suffices to prove that $L_f$ is topologically isomorphic to $Z \times H(K)$ where the space $Z$ is endowed with the left zero multiplication. Define an isomorphism $Φ : Z \times H(K) \to L_f$ assigning to each pair $(Z, x) ∈ Z \times H(K)$ the function $g_{Z,x} : [B] \to [Z]$ is the unique equivariant function such that $g_{Z,x}(B) = x^{-1}Z$. It is easy to check that $Φ$ is a topological isomorphism between $Z \times H(K)$ and $L_f$. ■

In the following proposition we prove the existence of continuous or discontinuous minimal idempotents in the semigroup $\text{End}(T_K)$. Let us recall that for a left-invariant ideal $I$ on a group $X$ we denote by $\text{End}^I(T_K)$ the left ideal in $\text{End}(T_K)$ consisting of all equivariant $I$-saturated functions.

Proposition 14.5. Let $I$ be a left-invariant ideal on a group $X$ and assume that a maximal 2-cogroup $K \subset X$ has finite characteristic group $H(K)$. Then the semigroup $\text{End}^I(T_K)$ contains:

1. a continuous minimal idempotent if $Kx \notin I$ for all $x ∈ X$;
2. no continuous function if $Kx ∈ I$ for all $x ∈ X$;
3. no discontinuous function (which is a minimal idempotent) if (and only if) for each $A ∈ T_K$ the set $\overline{A}^I \cap T_K$ is open in $T_K$.

Proof. By Proposition [12.2] the orbit space $[T_K]$ is compact, Hausdorff, and zero-dimensional, and the orbit map $q : T_K → [T_K]$ has a continuous section $s : [T_K] → T_K$. Then $Z = s([T_K])$ is a closed subset of $T_K$ that meets each orbit $[A]$, $A ∈ T_K$, in a single point. Pick any $B ∈ Z$ and define a continuous minimal idempotent $f : T_K → T_K$ letting $f(xZ) = xB$ for each $x ∈ H(K)$ and $Z ∈ Z$.

1. Assuming that $Kx \notin I$ for all $x ∈ X$, we shall show that the function $f$ is $I$-saturated and hence belongs to $\text{End}^I(T_K)$. Given any sets $A, B ∈ T_K$ with $A =_T B$, we need to show that $f(A) = f(B)$. We shall prove more: $A = B$. Assume that $A \neq B$ and pick $x ∈ A \triangle B$. Since $KKx = \text{Fix}(A)A = A$ and $KKB = \text{Fix}(B)B = B$, we get $KKx ∈ A \triangle B ∈ I$ and so for every $y ∈ K$, we get $Kyx = KKx ∈ I$, which contradicts our assumption.

2. Now assume that $Kx ∈ I$ for all $x ∈ X$. We shall prove that no function $g : \text{End}^I(T_K)$ is continuous. For this we show that for each $A ∈ T_K$ the set $\overline{A}^I \cap T_K$ is dense in $T_K$. Given any set $C ∈ T_K$ and a neighborhood $O(C)$ of $C$ in $T_K$, we need to find a set $B ∈ O(C)$ such that $B =_T A$. By the definition of the topology on $T_K \subset P(X)$, there is a finite subset $F ⊂ X$ such that $O(C) ⊃ \{B ∈ T_K : B \cap F = C \cap F\}$. Now we see that the set $B = (A \setminus K^±F) \cup (K^±F \cap C) ∈ T_K$ belongs to the neighborhood $O(C)$ and $B =_T A$ because $A \triangle B ⊂ K^±F ∈ I$. Assuming that some $I$-saturated equivariant function $g : T_K → T_K$ is continuous, we conclude that the preimage $g^{-1}(f(A)) ⊃ \overline{A}^I \cap T_K$ coincides with $T_K$, being a closed dense subset of $T_K$. So, $g$ is constant. Since the action of the (non-trivial) group $H(K)$ on $T_K$ is free, the constant map $g$ cannot be equivariant.

3. If for every $A ∈ T_K$ the set $\overline{A}^I \cap T_K$ is open in $T_K$, then each $I$-saturated function is locally constant and hence continuous. So, $\text{End}^I(T_K)$ contains no discontinuous function.
Now assuming that for some $A \in T_K$ the set $A = \tilde{A}^T \cap T_K$ is not open in $T_K$, we shall construct a discontinuous minimal idempotent $f \in \text{End}^T(T_K)$. Take any minimal idempotent $f \in \text{End}^T(T_K)$. If $f$ is discontinuous, we are done. So assume that $f$ is continuous and fix $B \in f(T_K)$. By Theorem [14.15], $f(T_K) = \{B\}$ is finite. So, $Z = f^{-1}(B)$ is open-and-closed in $T_K$. Take any $x \in \text{Stab}(K) \setminus KK$ and consider the subset $Z' = (Z \setminus A) \cup xA$ which is not compact as $A$ is not open in $Z$. Then the $T$-saturated minimal idempotent $g : T_K \to T_K$ defined by $g(xZ) = xB$ for $x \in H(K)$ and $Z \in Z'$ is discontinuous (because $g^{-1}(B) = Z'$ is not closed in $T_K$). ■

Corollary 14.6. For a maximal 2-cogroup $K \subset X$ and a left-invariant ideal $I$ on $X$ the following conditions are equivalent:

1. each minimal left ideal of $\text{End}^T(T_K)$ is a topological semigroup;
2. each minimal left ideal of $\text{End}^T(T_K)$ is a semitopological semigroup;
3. for each $A \in T_K$ the set $\tilde{A}^T \cap T_K$ is open in $T_K$.

If the ideal $I$ is right-invariant, then conditions (1)–(3) are equivalent to

4. $K$ has finite index in $X$;
5. the semigroup $\text{End}(T_K)$ is finite.

Proof. The equivalence (1)$\Leftrightarrow$(2)$\Leftrightarrow$(3) follows from Theorem [14.3] and Proposition [14.5].

Now assume that the left-invariant ideal $I$ is right-invariant.

(3)$\Rightarrow$(4) Assume that for each $A \in T_K$ the set $\tilde{A}^T \cap T_K$ is open in $T_K$. Then it is also closed in $T_K$ being the complement of the union of the open subsets $B^T \cap T_K$ for $B \neq I$. By Proposition [14.5], $Kx \notin I$ for some $x \in X$. Since the ideal $I$ is right-invariant, $Kx \notin I$ for all $x \in X$. We claim that the set $\tilde{A}^T \cap T_K = \{A\}$. Assuming that $\tilde{A}^T \cap T_K$ contains a set $B$ distinct from $A$, we can find a point $x \in A \Delta B$. Since $\text{Fix}(A) = KK = \text{Fix}(B)$, we get $KKx \subset KKA \Delta KKB = A \Delta B \in I$ and thus for any point $z \in K$, we arrive at the absurd conclusion $Kzx = KKx \in I$. Since the singleton $\tilde{A}^T \cap T_K = \{A\}$ is open in the space $T_K$, which is homeomorphic to $2^X/K^\pm$, the index of the group $K^\pm$ in $X$ is finite and so is the index of $K$ in $X$.

The implications (4)$\Rightarrow$(5)$\Rightarrow$(1) are trivial. ■

15. The semigroup $\text{End}_\lambda(T_K)$

In the preceding section we studied the continuity of the semigroup operation on minimal left ideals of the semigroup $\text{End}(T_K)$. In this section we shall be interested in the continuity of the semigroup operation on the semigroup $\text{End}_\lambda(T_K) \subset \text{End}(T_K)$. This will be done in a more general context of upper subfamilies $F \subset T$. We define a family $F \subset T$ to be upper if for any twin set $A \in F$ and a twin subset $B \subset X$ with $\text{Fix}^-(A) \subset \text{Fix}^-(B)$, we have $B \in F$.

Let us remark that $\hat{T}$ is an upper subfamily of $T$ while $T_K$ is a minimal upper subfamily of $T$ for every $K \in \hat{\mathcal{K}}$.

Proposition 15.1. Each upper subfamily $F \subset T$ is symmetric and $\lambda$-invariant. Consequently, $\text{End}_\lambda(F)$ is a compact right-topological semigroup.
Proof. To prove that $F \subset T$ is symmetric, given any set $A \in F$ choose a point $x \in \text{Fix}^{-}(A)$.
By Proposition 5.4, $\text{Fix}^{-}(xA) = x\text{Fix}^{-}(A)x^{-1} = \text{Fix}^{-}(A)$ and hence $X \setminus A = xA \in F$.

To see that $F$ is $\lambda$-invariant, we need to show that $\varphi(F) \subset F$ for any function $\varphi \in \text{End}_{\lambda}(P(X))$. By Corollary 4.4 the function $f$ is symmetric and left-invariant. Then for each $A \in F$ and $x \in \text{Fix}^{-}(A)$ we get $x\varphi(A) = \varphi(xA) = \varphi(X \setminus A) = X \setminus \varphi(A)$ and hence $x \in \text{Fix}^{-}(\varphi(A))$. Since $\text{Fix}^{-}(A) \subset \text{Fix}^{-}(\varphi(A))$, the set $\varphi(A)$ belongs to $F$ by the definition of an upper family.

\textbf{Theorem 15.2.} For an upper subfamily $F \subset T$ the following conditions are equivalent:

1. $\text{End}_{\lambda}(F)$ is a topological semigroup;
2. $\text{End}_{\lambda}(F)$ is a semitopological semigroup;
3. for each twin set $A \in F$ the subgroup $\text{Fix}(A)$ has finite index in $X$.

Proof. (3) $\Rightarrow$ (1) Assume that for each twin set $A \in F$ the stabilizer $\text{Fix}(A)$ has finite index in $X$. To show that the semigroup operation $\circ : \text{End}_{\lambda}(F) \times \text{End}_{\lambda}(F) \to \text{End}_{\lambda}(F)$ is continuous, fix any two functions $f, g \in \text{End}_{\lambda}(F)$ and a neighborhood $O(f \circ g)$ of their composition. We should show that the functions $f, g$ have neighborhoods $O(f), O(g) \subset \text{End}_{\lambda}(F)$ such that $O(f) \circ O(g) \subset O(f \circ g)$. We lose no generality assuming that the neighborhood $O(f \circ g)$ is of subbasic form:

$$O(f \circ g) = \{h \in \text{End}_{\lambda}(F) : x \in h(A)\}$$

for some $x \in X$ and some twin set $A \in F$. Let $B = g(A)$. It follows from $f \circ g \in O(f \circ g)$ that $x \in f \circ g(A) = f(B)$. Let $O(f) = \{h \in \text{End}_{\lambda}(F) : x \in h(B)\}$.

The definition of $O(g)$ is a bit more complicated. By our hypothesis, the stabilizer $\text{Fix}(A)$ has finite index in $X$. Let $S \subset X$ be a (finite) subset meeting each coset $\text{Fix}(A)z$, $z \in X$, in a single point. Consider the following open neighborhood of $g$ in $\text{End}_{\lambda}(F)$:

$$O(g) = \{g' \in \text{End}_{\lambda}(F) : \forall s \in S \ (s \in B \Leftrightarrow s \in g'(A))\}.$$ 

We claim that $O(f) \circ O(g) \subset O(f \circ g)$. Indeed, take any functions $f' \in O(f)$ and $g' \in O(g)$. By Theorem 11.1, $\text{Fix}^{-}(A) \subset \text{Fix}^{-}(g'(A))$ and hence $\text{Fix}(A) \subset \text{Fix}(g'(A))$. Then $g'(A) = \text{Fix}(A) \cdot (S \cap g'(A)) = \text{Fix}(A) \cdot (S \cap B) = B$ and thus $x \in f'(B) = f' \circ g'(A)$, witnessing that $f' \circ g' \in O(f \circ g)$.

The implication (1) $\Rightarrow$ (2) is trivial.

(2) $\Rightarrow$ (3) Assume that $X$ contains a twin subset $T_{0} \in F$ whose stabilizer $\text{Fix}(T_{0})$ has infinite index in $X$. Then the subgroup $H = \text{Fix}^{\pm}(T_{0})$ also has infinite index in $X$. By Theorem 15.5 of \textbf{[18]}, $X \neq \text{FHF}$ for any finite subset $F \subset C$.

\textbf{Lemma 15.3.} There are countable sets $A, B \subset X$ such that

1. $xB \cap yB = \emptyset$ for any distinct $x, y \in A$;
2. $|AB \cap Hz| \leq 1$ for all $z \in X$;
3. $e \in A$, $AB \cap H = \emptyset$.

Proof. Let $a_{0} = e$ and $B_{<0} = \{e\}$. Inductively we shall construct sequences $A = \{a_{n} : n \in \omega\}$ and $B = \{b_{n} : n \in \omega\}$ such that

- $b_{n} \notin A_{<n}^{-1}HA_{\leq n}B_{<n}$ where $A_{\leq n} = \{a_{i} : i \leq n\}$ and $B_{\leq n} = \{e\} \cup \{b_{i} : i < n\}$;
- $a_{n+1} \notin HA_{\leq n}B_{\leq n}B_{\leq n}^{-1}$.
Since \( X \neq FHF \) for any finite subset \( F \subset X \), the choice of the points \( b_n \) and \( a_{n+1} \) at the \( n \)-th step is always possible. It is easy to check that the sets \( A, B \) satisfy conditions (1)–(3) of the lemma.  

The properties (2), (3) of the set \( AB \) allows us to enlarge \( AB \) to a subset \( S \) that contains the neutral element of \( X \) and meets each coset \( Hz \), \( z \in X \), in a single point. Observe that each subset \( E \subset S \) generates a twin subset 

\[
T_E = \text{Fix}(T_0) \cdot E \cup \text{Fix}^- (T_0) \cdot (S \setminus E)
\]

of \( X \) such that \( \text{Fix}^- (T_0) \subset \text{Fix}^- (T_E) \) and hence \( T_E \in \mathcal{F} \).

**Lemma 15.4.** There is a free ultrafilter \( \mathcal{B} \) on \( X \) and a family of subsets \( \{ U_a : a \in A \} \subset \mathcal{B} \) such that

1. \( \bigcup_{a \in A} U_a \subset B \);
2. the set \( U = \bigcup_{a \in A} aU_a \) has the property \( B \not\subset x^{-1} U \cup y^{-1} U \) for every \( x, y \in A \);
3. for every \( V \in \mathcal{B} \) the set \( \{ a \in A : aV \subset U \} \) is finite.

**Proof.** Let \( A = \{ a_n : n \in \omega \} \) and \( B \) be the sets constructed in Lemma 15.3. For every \( n \in \omega \) put \( A_{\leq n} = \{ a_i : i \leq n \} \). Let \( B_{<0} = \{ e \} \) and inductively, for every \( n \in \omega \) choose an element \( b_n \in B \) so that

\[
b_n \notin A_{\leq n}^{-1} A_{\leq n} B_{<n} \quad \text{where} \quad B_{<n} = \{ b_i : i < n \}.
\]

For every \( n \in \omega \) let \( B_{\geq n} = \{ b_i : i \geq n \} \). Let also \( B_{2\omega} = \{ b_{2n} : n \in \omega \} \).

Let us show that for any distinct numbers \( n, m \) the intersection \( a_nB_{\geq n} \cap a_mB_{\geq m} \) is empty. Otherwise there would exist two numbers \( i \geq n \) and \( j \geq m \) such that \( a_nb_i = a_mb_j \). It follows from \( a_n \neq a_m \) that \( i \neq j \). We lose no generality assuming that \( j > i \). Then \( a_nb_i = a_mb_j \) implies that

\[
b_j = a_m^{-1} a_nb_i \in A_{\leq j}^{-1} A_{\leq j} B_{<j},
\]

which contradicts the choice of \( b_j \).

Let \( \mathcal{B} \in \beta(X) \) be any free ultrafilter such that \( B_{2\omega} \in \mathcal{B} \) and \( \mathcal{B} \) is not a P-point in \( \beta(X) \setminus X \). To get such an ultrafilter, take \( \mathcal{B} \) to be a cluster point of any countable subset of \( \beta(B_{2\omega}) \setminus B_{2\omega} \subset \beta(X) \). Using the fact that \( \mathcal{B} \) fails to be a P-point, we can take a decreasing sequence of subsets \( \{ V_n : n \in \omega \} \subset \mathcal{B} \) of \( B_{2\omega} \) having no pseudointersection in \( \mathcal{B} \). The latter means that for every \( V \in \mathcal{B} \) the almost inclusion \( V \subset^* V_n \) (which means that \( V \setminus V_n \) is finite) holds only for finitely many numbers \( n \).

For every \( a = a_n \in A \) let \( U_a = V_n \cap B_{\geq n} \). We claim that the ultrafilter \( \mathcal{B} \), the family \( (U_a)_{a \in A} \), and the set \( U = \bigcup_{a \in A} aU_a = \bigcup_{n \in \omega} a_n(V_n \cap B_{\geq n}) \) satisfy the requirements of the lemma.

First, we check that \( B \not\subset a_n^{-1} U \cup a_m^{-1} U \) for all \( n \leq m \). Take any odd number \( k > m \). We claim that \( b_k \notin a_n^{-1} U \cup a_m^{-1} U \). Otherwise, \( b_k \in a_n^{-1} a_i(V_i \cap B_{\geq i}) \cup a_m^{-1} a_i(V_i \cap B_{\geq i}) \) for some \( i \in \omega \) and hence \( b_k = a_n^{-1} a_i b_j \) or \( b_k = a_m^{-1} a_i b_j \) for some even \( j \geq i \). If \( k > j \), then both the equalities are forbidden by the choice of \( b_k \notin A_{\leq k}^{-1} A_{\leq k} B_{<k} \supset \{ a_n^{-1} a_i b_j, a_m^{-1} a_i b_j \} \). If \( k < j \), then those equalities are forbidden by the choice of \( b_j \notin A_{\leq j}^{-1} A_{\leq j} B_{<j} \supset \{ a_i^{-1} a_n b_k, a_i^{-1} a_m b_k \} \). Therefore, \( B \not\subset a_n^{-1} U \cup a_m^{-1} U \).
Next, given an arbitrary \( V \in B \) we show that the set \( A' = \{ a \in A : aV \subset U \} \) is finite. By the choice of the sequence \( (V_n) \), the set \( F = \{ a_n : V \cap B_{2\omega} \subset \* V_n \} \) is finite. We claim that \( A' \subset F \). Indeed, take any \( a_n \in A' \). It follows from \( a_n V \subset U = \bigcup_{a \in A} aB_a \) and \( a_n B \cap \bigcap_{i \neq n} a_i B = \emptyset \) that
\[
a_n(V \cap B_{2\omega}) \subset \* a_n(V_n \cap B_{\geq n}) \subset a_n V_n
\]
and hence \( a_n \in F \). ■

Let \( A \) be any free ultrafilter on \( X \) containing the set \( A \) and observe that \( U = \bigcup_{a \in A} a(V_n \cap B_{\geq n}) \in A \circ B \). Let \( \alpha = \Phi_f(A) \) and \( \beta = \Phi_f(B) \) be the function representations of the ultrafilters \( A \) and \( B \), respectively. We claim that the left shift \( l_\alpha : \text{End}_\lambda(F) \to \text{End}_\lambda(F) \), \( l_\alpha : f \mapsto \alpha \circ f \), is discontinuous at \( \beta \). Since \( U \subset AB \subset S \), we can consider the twin set
\[
T = \text{Fix}(T_0) \cdot U \cup \text{Fix}^{-}(T_0) \cdot (S \setminus U)
\]
and observe that \( T \in A \circ B \). Consequently, \( \alpha \circ \beta(T) = \{ x \in G : x^{-1}T \in A \circ B \} \) contains the neutral element, which implies that \( O(\alpha \circ \beta) = \{ f \in \text{End}_\lambda(F) : e \in f(T) \} \) is a neighborhood of \( l_\alpha(\beta) = \alpha \circ \beta \) in \( \text{End}_\lambda(F) \).

Assuming that \( l_\alpha \) is continuous at \( \beta \), we can find a neighborhood \( O(\beta) \subset \text{End}_\lambda(F) \) of \( \beta \) such that \( l_\alpha(O(\beta)) \subset O(\alpha \circ \beta) \). Since \( F \) is left-invariant, we can assume that \( O(\beta) \) is of the basic form:
\[
O(\beta) = \left\{ f \in \text{End}_\lambda(F) : e \in \bigcap_{i=1}^{n} f(T_i) \right\}
\]
for some twin sets \( T_1, \ldots, T_n \in F \). It follows from \( \beta \in O(\beta) \) that \( e \in \beta(T_i) \) and thus \( T_i \in B \) for every \( i \leq n \). According to Lemma 15.4(3), the set \( F = \{ a \in A : B \cap \bigcap_{i=1}^{n} T_i \subset a^{-1}U \} \) is finite.

We claim that the family \( \mathcal{L} = \{ T_1, \ldots, T_n, X \setminus x^{-1}T : x \in A \setminus F \} \) is linked. This will follow as soon as we check that
(i) \( T_i \cap (X \setminus x^{-1}T) \neq \emptyset \) for any \( i \leq n \) and \( x \in A \setminus F \);
(ii) \( (X \setminus x^{-1}T) \cap (X \setminus y^{-1}T) \neq \emptyset \) for all \( x, y \in A \).

Item (i) is equivalent to \( T_i \nsubseteq x^{-1}T \) for \( x \in A \setminus F \). Assuming that \( T_i \subset x^{-1}T \), we will consecutively get \( xT_i \subset T \), \( S \cap xT_i \subset S \cap T = U \), and finally \( B \cap T_i \subset x^{-1}S \cap T_i \subset x^{-1}U \), which contradicts \( x \notin F \).

Item (ii) is equivalent to \( x^{-1}T \cup y^{-1}T \neq X \) for \( x, y \in A \). Assume that \( x^{-1}T \cup y^{-1}T = X \) for some \( x, y \in A \). It follows from \( xB \subset S \) that \( xB \cap T = xB \cap U \) and thus \( B \cap x^{-1}T = B \cap x^{-1}U \). Similarly, \( B \cap y^{-1}T = B \cap y^{-1}U \). Consequently,
\[
B = B \cap X = B \cap (x^{-1}T \cup y^{-1}T) = B \cap (x^{-1}U \cup y^{-1}U) \neq B
\]
by Lemma 15.4(2). This contradiction completes the proof that \( \mathcal{L} \) is linked.

Being linked, the family \( \mathcal{L} \) can be enlarged to a maximal linked system \( \mathcal{C} \in \lambda(X) \). It follows from \( T_1, \ldots, T_n \in \mathcal{L} \subset \mathcal{C} \) that the twin representation \( \gamma = \Phi_f(\mathcal{C}) \) belongs to the neighborhood \( O(\beta) \), and consequently \( \alpha \circ \gamma \in O(\alpha \circ \beta) \), which means that \( T \in A \circ \mathcal{C} \). The latter is equivalent to \( A' = \{ x \in X : x^{-1}T \in \mathcal{C} \} \in A \). On the other hand, \( X \setminus A' = \ldots \)
\{x \in X : X \setminus x^{-1}T \in \mathcal{C}\} contains the set \(A \setminus F \in \mathcal{A}\) and thus \(X \setminus A' \in \mathcal{A}\), which is a contradiction.

**Theorem 15.5.** If the group \(X\) is twinic, then for an upper subfamily \(F \subset T\) the following conditions are equivalent:

1. \(\text{End}_\lambda(F)\) is metrizable;
2. \(\text{End}_\lambda(F)\) is a metrizable topological semigroup;
3. \(F\) is at most countable.

**Proof.** We shall prove the implications (3) \(\Rightarrow\) (2) \(\Rightarrow\) (1) \(\Rightarrow\) (3).

(3) \(\Rightarrow\) (2) Assume that the family \(F\) is at most countable. We claim that for each twin subset \(T \in F\) the 2-cogroup \(K = \text{Fix}^-(T)\) has finite index in \(X\). Otherwise, the subgroup \(K^\pm = KK \cup K\) also has infinite index on \(X\) and then \(|F| \geq |T_K| = 2^{\left|X/K^\pm\right|} > 2^\omega \geq \aleph_0\).

So, \(\text{Fix}(T)\) has finite index in \(X\) and the implication (3) \(\Rightarrow\) (1) of Theorem 15.2 guarantees that \(\text{End}_\lambda(F)\) is a topological semigroup. Now we show that this space is metrizable. First observe that for every \(T \in F\) the set \(\text{End}_\lambda(T) = \{\varphi \mid \varphi \in \text{End}_\lambda(\mathcal{P}(X))\}\) has finite cardinality

\[|\text{End}_\lambda(T)| = \left|\{\varphi : \varphi \in \text{End}_\lambda(\mathcal{P}(X))\}\right| \leq |\{A \in T : \text{Fix}(A) \supset \text{Fix}(T)\}|.
\]

Since the family \(F\) is countable, the space \(\text{End}_\lambda(F) \subset \prod_{T \in F} \text{End}_\lambda(T)\) is metrizable, being a subspace of the countable product of finite discrete spaces.

The implication (2) \(\Rightarrow\) (1) is trivial.

(1) \(\Rightarrow\) (3) Assuming that the family \(F\) is not countable, we shall show that the space \(\text{End}_\lambda(F)\) is not metrizable. We consider two cases.

(a) For some twin set \(T \in F\) the stabilizer \(\text{Fix}(T)\) has infinite index. Then we can find an infinite set \(S \subset X\) that intersects each coset \(\text{Fix}^\pm(T)x, x \in X,\) in a single point. As we already know, for each subset \(E \subset S\) the set

\[T_E = \text{Fix}(T) \cdot E \cup \text{Fix}^-(T) \cdot (S \setminus E)
\]

belongs to the family \(F\). Now take any two distinct ultrafilters \(U, V \in \beta(S) \subset \beta(X)\) and consider their function representations \(f_U = \Phi_F(U)\) and \(f_V = \Phi_F(V)\). Since \(U \neq V\), there is a subset \(E \subset S\) such that \(E \in U \setminus V\). It follows that \(T_E \in U\) and \(T_{S \setminus E} \in V\), which implies \(T_E \notin V\) and hence \(e \in f_U(T_E) \setminus f_V(T_E)\). This means that \(f_U \neq f_V\) and consequently, \(|\text{End}_\lambda(F)| \geq |\beta(S)| \geq 2^\omega\), which implies that the compact space \(\text{End}_\lambda(F)\) is not metrizable (because each metrizable compact space has cardinality \(\leq \omega\)).

(b) For each \(T \in F\) the subgroup \(\text{Fix}(T)\) has finite index in \(X\). Then each set \(T \in F\) has finite orbit \([T] = \{xT : x \in X\}\). Consider the smallest left-invariant family \(\bar{F} = \bigcup_{T \in F} [T]\) that contains \(F\). By Proposition 13.4 the family \(\bar{F}\) is \(\{0\}\)-independent. Since each orbit \([T] = \bar{F}\), \(T \in \bar{F}\), is finite and \(F\) is uncountable, the orbit space \(\bar{F}/\bar{F}\) is also uncountable. It follows from Theorem 11.1 that the space \(\text{End}_\lambda(\bar{F})\) is homeomorphic to the product \(\prod_{[T] \in \bar{F}} \text{End}_\lambda([T])\) where each space \(\text{End}_\lambda([T])\) contains at least two equivariant functions: the identity \(i : [T] \rightarrow [T]\) and the antipodal \(\alpha : [T] \rightarrow [T]\), \(\alpha : A \mapsto X \setminus A\). Since the orbit space \(\bar{F}\) is uncountable, the product \(\prod_{[T] \in \bar{F}} \text{End}_\lambda([T])\) is non-metrizable and so is its topological copy \(\text{End}_\lambda(\bar{F})\).
It remains to observe that the restriction map $R : \text{End}_\lambda(F) \to \text{End}_\lambda(F)$ is injective and thus a homeomorphism. Indeed, given two distinct equivariant functions $f, g \in \text{End}_\lambda(F)$, we can find a set $A \in \mathbb{F}$ with $f(A) \neq g(A)$. Since $|A| \cap \mathbb{F} \neq \emptyset$, there is $x \in X$ such that $xA \in \mathbb{F}$. Then $f(xA) = xf(A) \neq xg(A) = g(xA)$ and thus $f|\mathbb{F} \neq g|\mathbb{F}$. 

The following proposition characterizes groups containing only countably many twin subsets. Following [4], we define a group $X$ to be odd if each $x \in X$ has odd order.

**Proposition 15.6.** The family $\mathbb{T}$ of twin subsets of a group $X$ is at most countable if and only if each subgroup of infinite index in $X$ is odd.

**Proof.** Assume that each subgroup of infinite index in $X$ is odd. We claim that for every $A \in \mathbb{T}$ the subgroup $\text{Fix}(A)$ has finite index in $X$. Take any point $c \in \text{Fix}^{-}(A)$ and consider the cyclic subgroup $c^\mathbb{Z} = \{c^n : n \in \mathbb{Z}\}$ generated by $c$. The subgroup $c^\mathbb{Z}$ has finite index in $X$, being non-odd. Since $c^{2^\mathbb{Z}} = \{c^{2n} : n \in \mathbb{Z}\} \subset \text{Fix}(A)$, we conclude that $\text{Fix}(A)$ also has finite index in $X$.

Next, we show that the family $\{\text{Fix}(A) : A \in \mathbb{T}\}$ is at most countable. This is trivially true if $\mathbb{T} = \emptyset$. If $\mathbb{T} \neq \emptyset$, then we can take any $A \in \mathbb{T}$ and choose a point $c \in \text{Fix}^{-}(A)$. The cyclic subgroup $c^\mathbb{Z}$ generated by $c$ is not odd and hence has finite index in $X$. Consequently, the group $X$ is at most countable. Now it remains to check that for every $x \in X$ the set $T_x = \{A \in \mathbb{T} : x \in \text{Fix}^{-}(A)\}$ is finite. If the set $T_x$ is not empty, then the cyclic subgroup $x^\mathbb{Z}$ generated by $x$ is not odd and hence has finite index in $X$. Consider the subgroup $x^{2^\mathbb{Z}}$ of index 2 in $x^\mathbb{Z}$. It is clear that $x^{2^\mathbb{Z}} \subset \text{Fix}(A)$. Let $S \subset X$ be a finite set containing the neutral element of $X$ and meeting each coset $x^{2^\mathbb{Z}}z$, $z \in X$, in a single point. It follows from $x^{2^\mathbb{Z}} \subset \text{Fix}(A)$ that $A = x^{2^\mathbb{Z}} \cdot (S \cap A)$ and consequently $|T_x| \leq 2^{|S|} < \infty$.

Now assume that some subgroup $H$ of infinite index in $X$ is not odd. Then $H$ contains an element $c \in H$ such that the sets $c^{2^\mathbb{Z}} = \{c^{2n} : n \in \mathbb{Z}\}$ and $c^{2^\mathbb{Z}+1} = \{c^{2n+1} : n \in \mathbb{Z}\}$ are disjoint. Their union coincides with the cyclic subgroup $c^\mathbb{Z}$ of $H$ generated by $c$. Find a set $S \subset X$ that intersects each coset $c^\mathbb{Z}x$, $x \in X$, in a single point. Since $c^{2^\mathbb{Z}}$ has infinite index in $X$, the set $S$ is infinite. Now observe that for every $E \subset S$ the union

$$T_E = c^{2^\mathbb{Z}} \cdot E \cup c^{2^\mathbb{Z}+1} \cdot (S \setminus E)$$

is a twin set with $c \in \text{Fix}^{-}(T_E)$. Consequently, $\mathbb{T} \supset \{T_E : E \subset S\}$ has cardinality

$$|\mathbb{T}| \geq |\{T_E : E \subset S\}| \geq 2^{|S|} \geq c > \aleph_0.$$ 

Now we shall apply the above results to the minimal upper subfamilies $\mathbb{T}_K$ with $K \in \widehat{\mathbb{K}}$. By Theorem 14.1, for a maximal 2-cogroup $K$ in a group $X$ minimal left ideals of $\text{End}(\mathbb{T}_K)$ are metrizable if and only if $|X/K| \leq \aleph_0$. The metrizability of the whole semigroup $\text{End}(\mathbb{T}_K)$ is equivalent to $|X/K| < \aleph_0$.

**Theorem 15.7.** For a maximal 2-cogroup $K$ of a twinic group $X$ the following conditions are equivalent:

1. $\text{End}_\lambda(\mathbb{T}_K)$ is metrizable;
2. $\text{End}_\lambda(\mathbb{T}_K)$ is a semitopological semigroup;
3. $\text{End}_\lambda(\mathbb{T}_K)$ is a finite semigroup;
(4) $\text{End}_\lambda(T_K) \text{ is isomorphic to } C_{2^k} \wr m^m \text{ or } Q_{2^k} \wr m^m \text{ for some } 1 \leq k \leq m < \infty$;

(5) $K$ has finite index in $X$.

Proof. The implications $(1) \Rightarrow (2) \Rightarrow (5)$ follow from Theorems 15.5 and 15.2

$(5) \Rightarrow (4)$ Assume that $K$ has finite index in $X$. Then the characteristic group $\mathcal{H}(K)$ of $K$ is finite and hence is isomorphic to $C_{2^k}$ or $Q_{2^k}$ for some $k \in \mathbb{N}$ (see Theorem 8.3). Also the set $T_K$ is finite and so is the orbit space $[T_K]$. By Theorem 14.1(3), the semigroup $\text{End}_\lambda(T_K)$ is isomorphic to $\mathcal{H}(K) \wr [T_K]$ and the latter semigroup is isomorphic to $C_{2^k} \wr m^m$ or $Q_{2^k} \wr m^m$ for $m = |[T_K]|$.

The implications $(4) \Rightarrow (3) \Rightarrow (1)$ are trivial. ■

16. Constructing nice idempotents in the semigroup $\text{End}_\lambda(P(X))$

In this section we prove the existence of some special idempotents in the semigroup $\text{End}_\lambda(P(X))$. These idempotents will help us to describe the structure of the minimal ideals of the semigroups $\text{End}_\lambda(P(X))$ and $\lambda(X)$ in Theorems 17.1 and Corollary 17.2.

In this section we assume that $\mathcal{I}$ is a left-invariant ideal in a group $X$. We recall that $p \mathcal{I}$ and $\mathcal{I}$ denote the families of $\mathcal{I}$-pretwin and $\mathcal{I}$-twin subsets of $X$, respectively. A function $f : F \to P(X)$ defined on a subfamily $F \subset P(X)$ is called $\mathcal{I}$-saturated if $f(A) = f(B)$ for any sets $A \equiv B$ in $F$.

**Proposition 16.1.** There is an idempotent $e_\mathcal{I} \in \text{End}_\lambda(P(X))$ such that

- $e_\mathcal{I}(P(X) \setminus p \mathcal{I}) \subset \{\emptyset, X\}$;
- $e_\mathcal{I}|p \mathcal{I} = \text{id}|p \mathcal{I}$;
- the function $e_\mathcal{I}$ restricted to $P(X) \setminus p \mathcal{I}$ is $\mathcal{I}$-saturated.

**Proof.** Consider the family $\mathcal{N}_X^\mathcal{I}(X) \subset P^2(X)$ of left-invariant $\mathcal{I}$-saturated linked systems on $X$, partially ordered by the inclusion relation. This set is not empty because it contains the invariant $\mathcal{I}$-saturated linked system $\{X \setminus A : A \in \mathcal{I}\}$. By Zorn’s Lemma, the partially ordered set $\mathcal{N}_X^\mathcal{I}(X)$ contains a maximal element $\mathcal{L}$, which is a maximal invariant $\mathcal{I}$-saturated linked system on the group $X$. By the maximality, the system $\mathcal{L}$ is monotone. Now consider the family

$$\mathcal{L}^\perp = \{A \subset X : \forall L \in \mathcal{L} \ (A \cap L \neq \emptyset)\}.$$

**Claim 16.2.** $\mathcal{L}^\perp \setminus \mathcal{L} \subset p \mathcal{I}$.

**Proof.** Fix any set $A \in \mathcal{L}^\perp \setminus \mathcal{L}$. First we check that $x A \cap A \in \mathcal{I}$ for some $x \in X$. Assuming the contrary, we would conclude that the family $\mathcal{A} = \{A' \subset X : \exists x \in X \ (A' \equiv x A)\}$ is invariant, $\mathcal{I}$-saturated and linked, and so is the union $\mathcal{A} \cup \mathcal{L}$, which is not possible by the maximality of $\mathcal{L}$. So, there is $x \in X$ with $x A \cap A \in \mathcal{I}$, which is equivalent to $x A \subset x X \setminus A$.

Next, we find $y \in X$ such that $A \cup y A \equiv X$, which is equivalent to $X \setminus A \subset x X \setminus A$. Assuming that no such $y$ exists, we conclude that for any $x, y \in X$ we have $x A \cup y A \neq x X \setminus A$. Then $(X \setminus x A) \cap (X \setminus y A) = X \setminus (x A \cup y A) \notin \mathcal{I}$, which means that the family $B = \{B \subset X : \exists x \in X \ (B \equiv X \setminus x A)\}$ is invariant $\mathcal{I}$-saturated and linked. We claim that $X \setminus A \in \mathcal{L}^\perp$. Assuming otherwise, we would conclude that $X \setminus A$ misses some set
Consider the function representation $\Phi_{\mathcal{L}} : \mathcal{P}(X) \to \mathcal{P}(X)$ of $\mathcal{L}$. By Propositions 4.3 and 4.5, the function $\Phi_{\mathcal{L}}$ is equivariant, monotone, $\mathcal{I}$-saturated, and $\Phi_{\mathcal{L}}(\mathcal{P}(X)) \subset \{\emptyset, X\}$.

It is clear that the function $e_{\mathcal{I}} : \mathcal{P}(X) \to \mathcal{P}(X)$ defined by

$$e_{\mathcal{I}}(A) = \begin{cases} A & \text{if } A \in p_{\mathcal{I}}^T, \\ \Phi_{\mathcal{L}}(A) & \text{otherwise} \end{cases}$$

has properties (1)–(3) of Proposition 16.1. It is also clear that $e_{\mathcal{I}} = e_{\mathcal{I}} \circ e_{\mathcal{I}}$ is an idempotent.

We claim that $e_{\mathcal{I}} \in \text{End}_{\lambda}(\mathcal{P}(X))$. By Corollary 4.4, we need to check that $e_{\mathcal{I}}$ is equivariant, monotone and symmetric. The equivariance of $e_{\mathcal{I}}$ follows from the equivariance of the maps $\Phi_{\mathcal{L}}$ and id.

To show that $e_{\mathcal{I}}$ is monotone, take any two subsets $A \subset B$ of $X$ and consider four cases.

1) If $A, B \notin p_{\mathcal{I}}^T$, then $e_{\mathcal{I}}(A) = \Phi_{\mathcal{L}}(A) \subset \Phi_{\mathcal{L}}(B) = e_{\mathcal{I}}(B)$ by the monotonicity of the function representation $\Phi_{\mathcal{L}}$ of the monotone family $\mathcal{L}$.

2) If $A, B \in p_{\mathcal{I}}^T$, then $e_{\mathcal{I}}(A) = A \subset B = e_{\mathcal{I}}(B)$.

3) $A \notin p_{\mathcal{I}}^T$ and $B \notin p_{\mathcal{I}}^T$. We claim that $B \in \mathcal{L}$. Assuming that $B \notin \mathcal{L}$ and applying Claim 16.2, we get $B \notin \mathcal{L}^\perp$. Then $B$ does not intersect some set $L \in \mathcal{L}$ and then $A \cap L = \emptyset$. It follows that the set $X \setminus A \supset L$ belongs to the maximal invariant $\mathcal{I}$-saturated linked system and so the set $yA \supset \mathcal{I} X \setminus A$ for some $y \in X$ (which exists as $A \in p_{\mathcal{I}}^T$). By the left-invariance of $\mathcal{L}$, we get $A \in \mathcal{L}$, which contradicts $X \setminus A \in \mathcal{L}$ and the linkedness of $\mathcal{L}$. This contradiction proves that $B \in \mathcal{L}$. In this case $e_{\mathcal{I}}(A) = A \subset X = \Phi_{\mathcal{L}}(B) = e_{\mathcal{I}}(B)$.

4) $A \notin p_{\mathcal{I}}^T$ and $B \in p_{\mathcal{I}}^T$. In this case we prove that $A \notin \mathcal{L}$. Assuming that $A \in \mathcal{L}$, we get $B \in \mathcal{L}$. Since $B \in p_{\mathcal{I}}^T$, there is a point $x \in X$ with $xB \subset \mathcal{I} X \setminus B$. Since $\mathcal{L}$ is left-invariant, monotone and $\mathcal{I}$-saturated, we conclude that $X \setminus B \in \mathcal{L}$, which contradicts $B \in \mathcal{L}$. Thus $A \notin \mathcal{L}$ and $e_{\mathcal{I}}(A) = \Phi_{\mathcal{L}}(A) = \emptyset \subset e_{\mathcal{I}}(B)$.

Finally, we show that the function $e_{\mathcal{I}}$ is symmetric. If $A \in p_{\mathcal{I}}^T$, then $X \setminus A \in p_{\mathcal{I}}^T$ and then $e_{\mathcal{I}}(X \setminus A) = X \setminus A = X \setminus e_{\mathcal{I}}(A)$.

Next, assume that $A \notin p_{\mathcal{I}}^T$. If $A \in \mathcal{L}$, then $X \setminus A \notin \mathcal{L}$ by the linkedness of $\mathcal{L}$. In this case $e_{\mathcal{I}}(X \setminus A) = \emptyset = X \setminus X = X \setminus e_{\mathcal{I}}(A)$.

If $A \notin \mathcal{L}$, then by Claim 16.2 $A \notin \mathcal{L}^\perp$ and thus $A$ is disjoint from some set $L \in \mathcal{L}$, which implies that $X \setminus A \in \mathcal{L}$. Then $e_{\mathcal{I}}(X \setminus A) = \Phi_{\mathcal{L}}(X \setminus A) = X = X \setminus \emptyset = X \setminus \Phi_{\mathcal{L}}(A) = X \setminus e_{\mathcal{I}}(A)$. ■

Our second special idempotent depends on a subfamily $\tilde{\mathcal{T}}$ of the family

$$\tilde{\mathcal{T}} = \{A \in \mathcal{T} : \text{Fix}^- (A) \in \hat{\mathcal{K}}\}$$

of twin sets with maximal 2-cogroup.
Theorem 16.3. If the ideal $\mathcal{I}$ is twinic, then for any $\mathcal{I}$-independent $\hat{\mathcal{K}}$-covering subfamily $\hat{T} \subset \hat{T}$ there is an idempotent $e_{\hat{T}} \in \text{End}^T_X(P(X))$ such that

1. $e_{\hat{T}}(P(X) \setminus T^T) \subset \emptyset, X$;
2. $e_{\hat{T}}(T^T) = \hat{T}$;
3. $e_{\hat{T}}(T^T) = \hat{T}$.

Proof. Let $e_{\mathcal{I}} : P(X) \rightarrow \emptyset, X \cup pT^T$ be the idempotent from Proposition 16.1. Since the ideal $\mathcal{I}$ is twinic, $pT^T = T^T$. The idempotent $e_{\hat{T}}$ will be defined as the composition $e_{\hat{T}} = \varphi \circ e_{\mathcal{I}}$ where $\varphi : \emptyset, X \cup T^T \rightarrow \emptyset, X \cup \hat{T}$ is an equivariant $\mathcal{I}$-saturated function such that

1. $\varphi \circ \varphi = \varphi$;
2. $\varphi(\emptyset, X \cup \hat{T}) = \text{id}$;
3. $\varphi(T^T) \subset \hat{T}$;
4. $\mathcal{I}$-Fix$^-(A) \subset \text{Fix}^-(\varphi(A))$ for all $A \in T^T$.

To construct such a function $\varphi$, consider the family $\mathcal{F}$ of all possible functions $\varphi : D_{\varphi} \rightarrow \emptyset, X \cup \hat{T}$ such that

a. $\{\emptyset, X\} \cup \hat{T} \subset D_{\varphi} \subset \emptyset, X \cup T^T$;
b. the set $D_{\varphi}$ is left-invariant;
c. $\varphi$ is equivariant and $\mathcal{I}$-saturated;
d. $\varphi(\emptyset, X \cup \hat{T}) = \text{id}$;
e. $\mathcal{I}$-Fix$^-(A) \subset \text{Fix}^-(\varphi(A))$ for all $A \in D_{\varphi}$.

The family $\mathcal{F}$ is partially ordered by the relation $\varphi \leq \psi$ defined by $\psi|D_{\varphi} = \varphi$.

The set $\mathcal{F}$ is not empty because it contains the identity function id of $\emptyset, X \cup \hat{T}$, which is $\mathcal{I}$-saturated because of the $\mathcal{I}$-independence of the family $\hat{T}$. By Zorn’s Lemma, $\mathcal{F}$ contains a maximal element $\varphi : D_{\varphi} \rightarrow \emptyset, X \cup \hat{T}$. We claim that $D_{\varphi} = \emptyset, X \cup T^T$.

Assuming otherwise, fix a set $A \in T^T \setminus D_{\varphi}$ and define a family $D_{\psi} = D_{\varphi} \cup \{xA : x \in X\}$. Next, we shall extend $\varphi$ to a function $\psi : D_{\psi} \rightarrow \emptyset, X \cup \hat{T}$. We consider two cases.

1) Assume that $A =_{\mathcal{I}} B$ for some $B \in D_{\varphi}$. Then also $xA =_{\mathcal{I}} xB$ for all $x \in X$. In this case we define the function $\psi : D_{\psi} \rightarrow \emptyset, X \cup \hat{T}$ assigning to each set $C \in D_{\psi}$ the set $\varphi(D)$ where $D \in D_{\varphi}$ is any set with $D =_{\mathcal{I}} C$. It can be shown that the function $\psi : D_{\psi} \rightarrow \emptyset, X \cup \hat{T}$ belongs to the family $\mathcal{F}$, which contradicts the maximality of $\varphi$.

2) Assume that $A \neq_{\mathcal{I}} B$ for all $B \in D_{\varphi}$. By Proposition 7.3 the 2-cogroup $\mathcal{I}$-Fix$^-(A)$ lies in a maximal 2-cogroup $K \in \hat{\mathcal{K}}$. Since $\hat{T}$ is $\hat{\mathcal{K}}$-covering, there is a twin set $B \in \hat{T}$ such that Fix$^-(B) = K$. In this case define the function $\psi : D_{\psi} \rightarrow \hat{T}$ by the formula

\[
\psi(C) = \begin{cases} 
\varphi(C) & \text{if } C \in D_{\varphi}, \\
xB & \text{if } C =_{\mathcal{I}} xA \text{ for some } x \in X.
\end{cases}
\]

If $xA =_{\mathcal{I}} yA$ for some $x, y \in X$, then $y^{-1}x \in \mathcal{I}$-Fix$^-(A) \subset K = \text{Fix}^-(B)$ and thus $xB = yB$, which means that $\psi$ is well-defined and $\mathcal{I}$-saturated. Also it is clear that $\psi$ is equivariant and hence belongs to $\mathcal{F}$, which is forbidden by the maximality of $\varphi$.

Thus the maximal function $\varphi$ is defined on $D_{\varphi} = \emptyset, X \cup T^T$ and we can put $e_{\hat{T}} = \varphi \circ e_{\mathcal{I}}$ where $e_{\mathcal{I}} : P(X) \rightarrow \emptyset, X \cup pT^T = \emptyset, X \cup T^T$ is the idempotent constructed in
Proposition 16.1. It follows from the properties of the functions \( \varphi \) and \( e_T \) that the function \( e_T \) is equivariant and \( I \)-saturated. Since the ideal \( I \) is twinic, the family \( T^I = pT^I \) is \( I \)-incomparable (by Proposition 13.1) and hence the monotonicity of the function \( \varphi \) follows automatically from its being \( I \)-saturated. Then \( e_T \) is monotone as the composition of two monotone functions. By Corollary 4.4, \( e_T \in \text{End}_\lambda(P(X)) \). □

Theorem 16.3 and Proposition 13.5 imply:

**Corollary 16.4.** If the ideal \( I \) is twinic, then for each minimal \( \tilde{K} \)-covering family \( \tilde{T} \subset \tilde{T} \) there is an idempotent \( e_T \in \text{End}_\lambda(P(X)) \) such that

1. \( e_T(P(X) \setminus T^I) \subset \{\emptyset, X\} \);
2. \( e_T(T^I) = \tilde{T} \);
3. \( e_T|\{\emptyset, X\} \cup \tilde{T} = \text{id} \).

17. The minimal ideal of the semigroups \( \lambda(X) \) and \( \text{End}_\lambda(P(X)) \)

In this section we apply Corollary 16.4 to describe the structure of the minimal ideals of the semigroups \( \lambda(X) \) and \( \text{End}_\lambda(P(X)) \).

**Theorem 17.1.** For a twinic group \( X \) a function \( f \in \text{End}_\lambda(P(X)) \) belongs to the minimal ideal \( K(\text{End}_\lambda(P(X))) \) of the semigroup \( \text{End}_\lambda(P(X)) \) if and only if the following two conditions hold:

1. the family \( f(\tilde{T}) \) is minimal \( \tilde{K} \)-covering;
2. \( f(P(X)) \subset \{\emptyset, X\} \cup f(\tilde{T}) \).

**Proof.** Let \( \tilde{T} \subset \tilde{T} \) be a minimal \( \tilde{K} \)-covering left-invariant family and \( e_T \in \text{End}_\lambda(P(X)) \) be an idempotent satisfying conditions (1)–(3) of Corollary 16.4. By Propositions 13.1 and 13.5, the family \( \tilde{T} \) is \( I \)-incomparable and \( I \)-independent for any twinic ideal \( I \) on \( X \).

To prove the “if” part of the theorem, assume that \( f \) satisfies conditions (1) and (2). To show that \( f \) belongs to the minimal ideal \( K(\text{End}_\lambda(P(X))) \), it suffices for each \( g \in \text{End}_\lambda(P(X)) \) to find \( h \in \text{End}_\lambda(P(X)) \) such that \( h \circ g \circ f = f \).

The minimality and left-invariance of the \( \tilde{K} \)-covering subfamily \( f(\tilde{T}) \) imply that the equivariant function \( \psi = e_T \circ g \{\emptyset, X\} \cup f(\tilde{T}) : \{\emptyset, X\} \cup f(\tilde{T}) \to \{\emptyset, X\} \cup \tilde{T} \) is bijective. So, we can consider the inverse function \( \psi^{-1} : \{\emptyset, X\} \cup \tilde{T} \to \{\emptyset, X\} \cup f(\tilde{T}) \) such that \( \psi^{-1} \circ \psi = \text{id} \{\emptyset, X\} \cup f(\tilde{T}) \). This function is equivariant, symmetric, and monotone because so is \( \psi \) and the family \( \tilde{T} \) is \( I \)-incomparable and \( I \)-independent.

Then the function \( \varphi = \psi^{-1} \circ e_T : P(X) \to \{\emptyset, X\} \cup f(\tilde{T}) \) is well-defined and belongs to \( \text{End}_\lambda(P(X)) \) by Corollary 4.4. Since

\[
(\varphi \circ e_T) \circ g \circ f = \psi^{-1} \circ e_T \circ e_T \circ g \circ f = \psi^{-1} \circ e_T \circ g \circ f = \psi^{-1} \circ \psi \circ f = f,
\]
the function \( f \) belongs to the minimal ideal of the semigroup \( \text{End}_\lambda(P(X)) \).

To prove the “only if” part, take any \( f \in K(\text{End}_\lambda(P(X))) \) and for the idempotent \( e_T \in \text{End}_\lambda(P(X)) \) find \( g \in \text{End}_\lambda(P(X)) \) such that \( f = g \circ e_T \circ f \). Now the properties (1) and (2) of \( f \) follow from the corresponding properties of \( e_T \). □
Since the superextension $\lambda(X)$ of a group $X$ is topologically isomorphic to the semigroup $\text{End}_\lambda(P(X))$, Theorem 17.1 implies the following description of the minimal ideal $K(\lambda(X))$ of $\lambda(X)$.

**Corollary 17.2.** For a twinic group $X$ a maximal linked system $L \in \lambda(X)$ belongs to the minimal ideal $K(\lambda(X))$ of the superextension $\lambda(X)$ if and only if its function representation $\Phi_L$ satisfies two conditions:

1. The family $\Phi_L(\hat{T})$ is minimal $\hat{K}$-covering;
2. $\Phi_L(P(X)) \subseteq \{\emptyset, X\} \cup \Phi_L(\hat{T})$.

### 18. Minimal left ideals of superextensions of twinic groups

Having elaborated the necessary tools in Sections 5–17, we now return to describing the structure of minimal left ideals of the superextension $\lambda(X)$ of a twinic group $X$. In this section we assume that $X$ is a group.

Our first aim is to show that if the group $X$ is twinic, then the restriction operator $R_\hat{T} : \text{End}_\lambda(P(X)) \to \text{End}_\lambda(\hat{T})$ is injective on all minimal left ideals of the semigroup $\text{End}_\lambda(P(X))$. Since $\hat{T} = \bigcup_{K \in \hat{K}} T_K$, Proposition 12.3 implies that the family $\hat{T}$ is $\lambda$-invariant and hence $\text{End}_\lambda(\hat{T})$ is a compact right-topological semigroup. For each left-invariant ideal $I$ on the group $X$ the semigroup $\text{End}_\lambda(\hat{T})$ contains a left ideal $\text{End}_\lambda^I(\hat{T})$ consisting of all left-invariant monotone $I$-saturated functions (see Theorem 4.8). If $I$ is a twinic ideal with $I \cap \hat{K} = \emptyset$, then the family $\hat{T}$ is $I$-independent (see Proposition 13.3) and hence $\text{End}_\lambda^I(\hat{T}) = \text{End}_\lambda(\hat{T})$.

**Proposition 18.1.** If the group $X$ is twinic, then the restriction operator

$$R_\hat{T} : \text{End}_\lambda(P(X)) \to \text{End}_\lambda(\hat{T}), \quad R_\hat{T} : f \mapsto f|\hat{T},$$

is injective on each minimal left ideal of the semigroup $\text{End}_\lambda(P(X))$. If $\mathcal{I} \cap \hat{K} = \emptyset$, then for some idempotent $e_\hat{T} \in \text{End}_\mathcal{I}^P(P(X))$ the restriction $R_\hat{T}|\text{End}_\lambda(P(X)) \circ e_\hat{T}$ is a topological isomorphism between the principal left ideal $\text{End}_\lambda(P(X)) \circ e_\hat{T}$ and $\text{End}_\lambda(\hat{T})$.

**Proof.** Let $\tilde{T} \subset \hat{T}$ be any minimal $K$-covering left-invariant subfamily. By Propositions 13.5, the family $\tilde{T}$ is $\mathcal{I}$-independent. By Theorem 16.3 there is an idempotent $e_\tilde{T} \in \text{End}_\lambda^P(P(X))$ such that $e_\tilde{T}(P(X) \setminus \tilde{T}) \subseteq \{\emptyset, X\}$ and $e_\tilde{T}(\tilde{T}) = \tilde{T} \subset \hat{T}$. The latter property of $e_\tilde{T}$ implies that the restriction operator $R_\tilde{T}$ is injective on the principal left ideal $\text{End}_\lambda(P(X)) \circ e_\tilde{T}$, and consequently it is injective on each minimal left ideal of the semigroup $\text{End}_\lambda(P(X))$ according to Proposition 2.2.

If $\mathcal{I} \cap \hat{K} = \emptyset$, then by Proposition 13.3 the family $\hat{T}$ is $\mathcal{I}$-independent and we can repeat the above argument for the idempotent $e_\hat{T}$. 

Now let us look at the structure of the semigroup $\text{End}_\lambda(\hat{T})$. Observe that $\hat{T} = \bigcup_{[K] \in [\hat{K}]} T_{[K]}$, where $T_{[K]} = \{A \subset X : \text{Fix}^-(A) \in [K]\}$, $[\hat{K}] = \{[K] : K \in \hat{K}\}$ and $[K] = \{xKx^{-1} : x \in X\}$ for $K \in \hat{K}$. 
It follows that the restriction operators $R_{T[K]} : \text{End}_\lambda(T) \to \text{End}_\lambda(T[K]), [K] \in \mathcal{K}$, compose an injective semigroup homomorphism

$$R_{\mathcal{K}} : \text{End}_\lambda(T) \to \prod_{[K] \in \mathcal{K}} \text{End}_\lambda(T[K]), \quad R_{\mathcal{K}} : \varphi \mapsto (\varphi|_T)_K_{K \in \mathcal{K}}.$$

Theorem 11.1 implies

**Lemma 18.2.** For any twinic ideal $I$ on the group $X$ we get

$$R_{\mathcal{K}}(\text{End}_\lambda(T)) = \prod_{[K] \in \mathcal{K}} \text{End}_\lambda(T[K]).$$

Next, we study the structure of the semigroups $\text{End}_\lambda(T[K])$ for $[K] \in \mathcal{K}$.

**Lemma 18.3.** For any maximal 2-cogroup $K \in \mathcal{K}$ the restriction map

$$R_{T[K]} : \text{End}_\lambda(T[K]) \to \text{End}_\lambda(T_K), \quad R_{T[K]} : \varphi \mapsto \varphi|_{T_K},$$

is a topological isomorphism.

**Proof.** By the compactness of $\text{End}_\lambda(T[K])$ it suffices to check that the restriction operator $R_{T[K]} : \text{End}_\lambda(T[K]) \to \text{End}_\lambda(T_K)$ is one-to-one. Given two distinct functions $f, g \in \text{End}_\lambda(T[K])$ find a twin set $A \in T[K]$ such that $f(A) \neq g(A)$. Since $\text{Fix}^{-1}(A) \in [K]$, there is $x \in X$ such that $\text{Fix}^{-1}(xA) = x\text{Fix}^{-1}(A)x^{-1} = K$. By Proposition 5.4, $xA \in T_K$ and $f(xA) = xf(A) \neq xg(A) = g(xA)$, witnessing that $f|T_K \neq g|T_K$. \[\square\]

A subfamily $\mathcal{K} \subset \mathcal{K}$ is called a $[\mathcal{K}]$-selector if $\mathcal{K}$ has one-point intersection with each orbit $[K] = \{xKx^{-1} : x \in X\}$, $K \in \mathcal{K}$. In the following theorems we assume that $\mathcal{K} \subset \mathcal{K}$ is a $[\mathcal{K}]$-selector.

All the preceding discussion culminates in the following theorem, which can be considered as the main result of this paper.

**Theorem 18.4.** Given a $[\mathcal{K}]$-selector $\mathcal{K} \subset \mathcal{K}$, consider the operator

$$R_{\mathcal{K}} : \text{End}_\lambda(P(X)) \to \prod_{K \in \mathcal{K}} \text{End}(T_K), \quad R_{\mathcal{K}} : f \mapsto (f|_{T_K})_{K \in \mathcal{K}}.$$

If $I$ is a left-invariant twinic ideal on $X$, then

1. $R_{\mathcal{K}}(\text{End}_\lambda(P(X))) = \prod_{K \in \mathcal{K}} \text{End}_\lambda(T_K)$;
2. the operator $R_{\mathcal{K}}$ maps isomorphically each minimal left ideal of the semigroup $\text{End}_\lambda(P(X))$ onto some minimal left ideal of the semigroup $\prod_{K \in \mathcal{K}} \text{End}(T_K)$;
3. if $I \cap \mathcal{K} = \emptyset$, then for some idempotent $\hat{e} \in \text{End}_\lambda(P(X))$ and the principal left ideal $L_{\hat{e}} = \text{End}_\lambda(P(X)) \circ \hat{e}$ the restriction

$$R_{\mathcal{K}}|_{L_{\hat{e}}} : L_{\hat{e}} \to \prod_{K \in \mathcal{K}} \text{End}(T_K)$$

is a topological isomorphism.

**Proof.** Write the operator $R_{\mathcal{K}}$ as the composition $R_{\mathcal{K}} = R_{\mathcal{K}}^T \circ R_{\mathcal{T}}$ of two operators:

$$R_{\mathcal{T}} : \text{End}_\lambda(P(X)) \to \text{End}_\lambda(T), \quad R_{\mathcal{T}} : f \mapsto f|_{\tilde{T}},$$

$$R_{\mathcal{T}} : \text{End}_\lambda(T) \to \prod_{[K] \in \mathcal{K}} \text{End}_\lambda(T[K]), \quad R_{\mathcal{T}} : \varphi \mapsto (\varphi|_T)_K_{K \in \mathcal{K}}.$$
and

\[ R^K_{\tilde{T}} : \text{End}_\lambda(\tilde{T}) \to \prod_{K \in \tilde{K}} \text{End}_\lambda(T_K), \quad R^K_{\tilde{T}} : f \mapsto (f|T_K)_{K \in \tilde{K}}. \]

By Lemma 18.3, the operator \( R^K_{\tilde{T}} \) is injective.

1. It follows from Lemmas 18.2 and 18.3 that

\[ R^K_{\tilde{T}}(\text{End}_\lambda^T(\text{P}(X))) = R^K_{\tilde{T}}(\text{End}_\lambda(\tilde{T})) = \prod_{K \in \tilde{K}} \text{End}_\lambda^T(T_K). \]

2. To prove the second item, fix any function \( f \in \text{K(End}_\lambda(\text{P}(X))) \) and consider the minimal left ideal \( \text{L}_f = \text{End}_\lambda(\text{P}(X)) \circ f \). We need to show that \( R^K_{\tilde{T}}(\text{L}_f) \) is a minimal left ideal in \( \prod_{K \in \tilde{K}} \text{End}(T_K) \).

For this pick any function \( g \in \text{K(End}_\lambda(\text{P}(X))) \) and consider the minimal left ideal \( \text{L}_g = \text{End}_\lambda(\text{P}(X)) \circ g = \text{End}_\lambda^T(\text{P}(X)) \circ g \).

By Proposition 18.1 the operator \( R^K_{\tilde{T}} : \text{End}_\lambda(\text{P}(X)) \to \text{End}_\lambda(\tilde{T}) \) is injective on each minimal left ideal. Consequently, the operator \( R^K_{\tilde{T}} = R^K_{\tilde{T}} \circ R^K_{\tilde{T}} \) is also injective on each minimal left ideal of the semigroup \( \text{End}_\lambda(\text{P}(X)) \). In particular, \( R^K_{\tilde{T}} \) is injective on the minimal left ideals \( \text{L}_f \) and \( \text{L}_g \). Since \( \text{L}_g \) is a minimal left ideal of the semigroup \( \text{End}_\lambda^T(\text{P}(X)) \), its image \( R^K_{\tilde{T}}(\text{L}_g) \) is a minimal left ideal of the semigroup \( \text{End}_\lambda^T(\tilde{T}) \). By Lemmas 18.2 and 18.3, \( R^K_{\tilde{T}} \) maps isomorphically the semigroup \( \text{End}_\lambda^T(\tilde{T}) \) onto \( \prod_{K \in \tilde{K}} \text{End}_\lambda(T_K) \), the image \( R^K_{\tilde{T}}(\text{L}_g) \) remains a minimal left ideal of the semigroup \( \prod_{K \in \tilde{K}} \text{End}_\lambda(T_K) \). Since the latter semigroup is a left ideal in \( \prod_{K \in \tilde{K}} \text{End}(T_K) \), the image \( R^K_{\tilde{T}}(\text{L}_g) \) remains a minimal left ideal of the semigroup \( \prod_{K \in \tilde{K}} \text{End}_\lambda(T_K) \). This minimal left ideal is equal to the product \( \prod_{K \in \tilde{K}} \text{L}_{g_K} \) where \( g_K = g|T_K \) and \( \text{L}_{g_K} = \text{End}(T_K) \circ g_K \). By the compactness of \( \text{L}_g \), the operator \( R^K_{\tilde{T}} \) maps isomorphically the minimal left ideal \( \text{L}_g \) onto the minimal left ideal \( \prod_{K \in \tilde{K}} \text{L}_{g_K} \) of the semigroup \( \prod_{K \in \tilde{K}} \text{End}(T_K) \).

Now let us look at the minimal left ideal \( \text{L}_f \). By Proposition 2.1, the right shift \( r_f : \text{L}_g \to \text{L}_f, r_f : h \mapsto h \circ f \), is a homeomorphism. So, there is a function \( \gamma \in \text{End}_\lambda(\text{P}(X)) \) such that \( f = \gamma \circ g \circ f \).

For every \( K \in \tilde{K} \) consider the restrictions \( f_K = f|T_K \) and \( \gamma_K = \gamma|T_K \), which belong to the semigroup \( \text{End}(T_K) \). It follows from \( f = \gamma \circ g \circ f \) that \( f_K = \gamma_K \circ g_K \circ f_K \). Since \( g_K \in \text{K(End}(T_K)) \), we conclude that \( f_K \) also belongs to the minimal ideal \( \text{K(End}(T_K)) \).

Then \( \text{L}_{f_K} = \text{End}(T_K) \circ f_K \) and \( \text{L}_{g_K} = \text{End}(T_K) \circ g_K \) are minimal left ideals in \( \text{End}(T_K) \). By Proposition 2.1, the right shift \( r_{f_K} : \text{L}_{g_K} \to \text{L}_{f_K}, r_{f_K} : h \mapsto h \circ f_K \), is a homeomorphism. The homeomorphisms \( r_{f_K}, K \in \tilde{K} \), compose a homeomorphism

\[ r_{f_K} : \prod_{K \in \tilde{K}} \text{L}_{g_K} \to \prod_{K \in \tilde{K}} \text{L}_{f_K}, \quad r_{f_K} : (h_K)_{K \in \tilde{K}} \mapsto (h_K \circ f_K)_{K \in \tilde{K}}. \]

Now consider the commutative diagram

\[
\begin{array}{ccc}
L_f & \xrightarrow{R^K_{\tilde{T}}|f} & \prod_{K \in \tilde{K}} L_{f_K} \\
\uparrow r_f & & \uparrow r_{f_K} \\
L_g & \xrightarrow{R^K_{\tilde{T}}|g} & \prod_{K \in \tilde{K}} L_{g_K}
\end{array}
\]
Since \( r_f, r_{\tilde{K}}, \) and \( R_{\tilde{K}}|_{L_f} \) are homeomorphisms, so is \( R_{\tilde{K}}|_{L_f} \). Consequently, the operator \( R_{\tilde{K}} \) maps isomorphically the minimal left ideal \( L_f = \text{End}_\lambda(P(X)) \circ f \) onto the minimal left ideal \( \prod_{K \in \tilde{K}} L_{f_K} = \prod_{K \in \tilde{K}} \text{End}(T_K) \circ (f|T_K) \) of the semigroup \( \prod_{K \in \tilde{K}} \text{End}(T_K) \).

3. Assume that \( I \cap \tilde{K} = \emptyset \). In this case \( \text{End}_\lambda^T(\tilde{T}) = \text{End}(\tilde{T}) \) by Proposition 13.3. By Proposition 18.1, for some idempotent \( \hat{e} \in \text{End}_\lambda^T(P(X)) \) the operator \( R_{\tilde{K}}^T \) maps isomorphically the principal left ideal \( \hat{L}_\hat{e} = \text{End}_\lambda(P(X)) \circ \hat{e} \) onto \( \text{End}_\lambda^T(\tilde{T}) = \text{End}(\tilde{T}) \).

By Lemma 18.2, the operator \( R_{\tilde{K}}^T : \text{End}_\lambda(\tilde{T}) \to \prod_{K \in \tilde{K}} \text{End}(T_K) = \prod_{K \in \tilde{K}} \text{End}(T_K) \) is an isomorphism. So, \( R_{\tilde{K}} \) maps isomorphically the principal left ideal \( \hat{L}_\hat{e} \) onto \( \prod_{K \in \tilde{K}} \text{End}(T_K) \).

Since the function representation \( \Phi : \lambda(X) \to \text{End}_\lambda(P(X)) \), \( \Phi : \mathcal{L} \mapsto \Phi_{\mathcal{L}} \), is a topological isomorphism, the preceding theorem implies:

**Corollary 18.5.** Given a \( [\tilde{K}] \)-selector \( \tilde{K} \subset \hat{K} \), consider the continuous semigroup homomorphism

\[
\Phi_{\tilde{K}} : \lambda(X) \to \prod_{K \in \tilde{K}} \text{End}(T_K), \quad \Phi_{\tilde{K}} : \mathcal{L} \mapsto (\Phi_{\mathcal{L}}|T_K)_{K \in \tilde{K}}.
\]

If the group \( X \) is twinic, then

1. \( \Phi_{\tilde{K}}(\text{End}_\lambda^T(\mathcal{L})) = \prod_{K \in \tilde{K}} \text{End}_\lambda^T(T_K) \);
2. the homomorphism \( \Phi_{\tilde{K}} \) maps isomorphically each minimal left ideal of the semigroup \( \lambda(X) \) onto some minimal left ideal of the semigroup \( \prod_{K \in \tilde{K}} \text{End}(T_K) \);
3. if \( \mathcal{I} \cap \tilde{K} = \emptyset \), then for some idempotent \( E \in \lambda(X) \) and the principal left ideal \( L_E = \lambda(X) \circ E \) the restriction

\[
\Phi_{\tilde{K}}|_{L_E} : L_E \to \prod_{K \in \tilde{K}} \text{End}(T_K)
\]

is a topological isomorphism.

**Corollary 18.6.** If the group \( X \) is twinic, then each minimal left ideal of \( \lambda(X) \) is topologically isomorphic to a minimal left ideal of \( \prod_{K \in \tilde{K}} \text{End}(T_K) \) and each minimal left ideal of \( \prod_{K \in \tilde{K}} \text{End}_\lambda^T(T_K) \) is topologically isomorphic to a minimal left ideal of \( \lambda(X) \).

**Proof.** Corollary 18.5(2) implies that each minimal left ideal of \( \lambda(X) \) is topologically isomorphic to a minimal left ideal of \( \prod_{K \in \tilde{K}} \text{End}(T_K) \). Now assume that \( L \) is a minimal left ideal of the semigroup \( \prod_{K \in \tilde{K}} \text{End}_\lambda^T(T_K) \). It follows from Corollary 18.5(1) that the preimage \( \Phi_{\tilde{K}}^{-1}(L) \) is a left ideal in \( \lambda(X) \) and hence a left ideal in \( \lambda(X) \). This left ideal contains some minimal left ideal \( L_\lambda \) whose image \( \Phi_{\tilde{K}} \) coincides with \( L \) (being a left ideal in \( L \)). By Corollary 18.5(2), the map \( \Phi_{\tilde{K}}|_{L_\lambda} : L_\lambda \to L \) is injective and by the compactness of \( L_\lambda \) is a topological isomorphism.

**Theorem 18.7.** Let \( X \) be a twinic group, \( \tilde{K} \subset \hat{K} \) be a \( [\tilde{K}] \)-selector, and \( E \in \lambda(X) \) be a minimal idempotent.

1. The maximal subgroup \( H_E = E \circ \lambda(X) \circ E \) has the following properties:
   a. \( H_E \) is algebraically isomorphic to \( \prod_{K \in \tilde{K}} H(K) \).
(b) $H_\mathcal{E}$ is topologically isomorphic to $\prod_{K\in\mathcal{K}} H(A_K)$ for any twin sets $A_K \in \Phi_\mathcal{E}(T_K)$, $K \in \mathcal{K}$;
(c) $H_\mathcal{E}$ is a compact topological group if and only if $H(K)$ is finite for every $K \in \mathcal{K}$.

(2) The minimal left ideal $L_\mathcal{E} = \lambda(X) \circ \mathcal{E}$ has the following properties:

(d) $L_\mathcal{E}$ is topologically isomorphic to the minimal left ideal $\prod_{K\in\mathcal{K}} \text{End}(T_K) \circ (\Phi_\mathcal{E}|T_K)$;
(e) $L_\mathcal{E}$ is homeomorphic to $\prod_{K\in\mathcal{K}} T_K$, which is homeomorphic to the Cantor discontinuum $\prod_{K\in\mathcal{K}} 2^{X/K}$;
(f) $L_\mathcal{E}$ is algebraically isomorphic to $\prod_{K\in\mathcal{K}} H(K) \times [T_K]$ where the orbit space $[T_K]$ of the $H(K)$-act on $T_K$ is endowed with the left zero multiplication;
(g) $L_\mathcal{E}$ is a topological semigroup iff $L_\mathcal{E}$ is a semitopological semigroup iff each restriction $\Phi_\mathcal{E}|T_K$, $K \in \mathcal{K}$, is a continuous function iff the maximal subgroup $H_\mathcal{E}$ and the idempotent band $E(L_\mathcal{E})$ of $L_\mathcal{E}$ are compact iff $L_\mathcal{E}$ is topologically isomorphic to $\prod_{K\in\mathcal{K}} H(K) \times [T_K]$.

Proof. Let $\Phi_\mathcal{E} \in \text{End}_\lambda(P(X))$ be the function representation of the minimal idempotent $\mathcal{E} \in K(\lambda(X))$. For every $K \in \mathcal{K}$ let $f_K = \Phi_\mathcal{E}|T_K$ and $L_{f_K} = \text{End}(T_K) \circ f_K$ be the principal left ideal in $\text{End}(T_K)$, generated by the function $f_K$. By Corollary 18.5 the minimal left ideal $L_\mathcal{E}$ is topologically isomorphic to a minimal left ideal of the semigroup $\prod_{K\in\mathcal{K}} \text{End}(T_K)$. This minimal ideal contains $(f_K)_{K\in\mathcal{K}}$ and hence is equal to the product $\prod_{K\in\mathcal{K}} L_{f_K}$. This proves statement (d) of the theorem. Now all the other statements follow from Theorems 14.1 and 14.3.

Theorem 18.7(b) is completed by the following theorem.

Theorem 18.8. Let $\tilde{\mathcal{K}} \subset \mathcal{K}$ be a $[\mathcal{K}]$-selector. If the group $X$ is twinic, then for any twin sets $A_K \in T_K$, $K \in \mathcal{K}$, the minimal ideal $K(\lambda(X))$ of $\lambda(X)$ contains a maximal subgroup $H_\mathcal{E}$, which is topologically isomorphic to $\prod_{K\in\mathcal{K}} H(A_K)$.

Proof. In the semigroup $\prod_{K\in\mathcal{K}} \text{End}^\mathcal{P}(T_K)$ choose a sequence of functions $(f_K)_{K\in\mathcal{K}}$ such that $f_K(T_K) \subset [A_K]$ for all $K \in \mathcal{K}$. This can be done in the following way. For every $K \in \mathcal{K}$ first choose any minimal idempotent $g_K \in K(\text{End}^\mathcal{P}(T_K))$. By Theorem 14.1(5), $g_K(T_K) \subset [B_K]$ for some twin set $B \in T_K$. Since $T_K$ is a free $H(K)$-act, we can choose an equivariant function $\varphi: [B_K] \rightarrow [A_K]$. Then the composition $f_K = \varphi \circ g_K$ is $\mathcal{P}$-saturated and has the required property: $f_K(T_K) \subset [A_K]$.

Consider the minimal left ideal $L_{f_K} = \prod_{K\in\mathcal{K}} \text{End}(T_K) \circ f_K$ and let $L = \Phi_{\mathcal{K}}^{-1}(L) \subset \lambda(X)$. By Corollary 18.5(1), $\Phi_{\mathcal{K}}(L) = L_{f_K}$. Now let $K(L)$ be the minimal ideal of the left ideal $L$. The image $\Phi_{\mathcal{K}}(K(L))$, being a left ideal in $L_{f_K}$, coincides with $L_{f_K}$. So, we can find a maximal linked system $\mathcal{L} \in K(L)$ such that $\Phi_{\mathcal{K}}(\mathcal{L}) = (f_K)_{K\in\mathcal{K}}$. By Theorem 18.7(b), the maximal group $H_\mathcal{E}$ is topologically isomorphic to $\prod_{K\in\mathcal{K}} H(A_K)$.

Proposition 18.9. If $X$ is a twinic group, then each minimal left ideal of $\lambda(X)$ is a topological semigroup if and only if each maximal 2-cogroup $K \subset X$ has finite index in $X$.

Proof. Let $\tilde{\mathcal{K}} \subset \mathcal{K}$ be a $[\mathcal{K}]$-selector. If each maximal 2-cogroup $K \subset X$ has finite index in $X$, then the set $T_K$ is finite and hence the semigroup $\text{End}(T_K)$ is finite. Consequently,
\[ \prod_{K \in \hat{\mathcal{K}}} \text{End}(T_K) \] is a compact topological semigroup and so is each minimal left ideal of this semigroup. By Corollary 18.5(2), each minimal left ideal of the semigroup \( \lambda(X) \) is a topological semigroup.

If some maximal 2-cogroup in \( X \) has infinite index, then Corollary 14.6 implies that some minimal left ideal in \( \prod_{K \in \hat{\mathcal{K}}} \text{End}^\mathcal{I}(T_K) \) is not a topological semigroup. By Corollary 18.6 some minimal left ideal in \( \lambda^\mathcal{I}(X) \) is not a topological semigroup.

**Proposition 18.10.** For a twinic group \( X \) with \( \mathcal{I} \cap \hat{\mathcal{K}} = \emptyset \) the following conditions are equivalent:

1. some minimal left ideal of \( \lambda(X) \) is a topological semigroup;
2. each maximal subgroup of \( \lambda(X) \) is a topological group;
3. some maximal subgroup of \( \lambda(X) \) is compact;
4. the characteristic group \( H(K) \) is finite for each maximal 2-cogroup \( K \subset X \).

**Proof.** (1)\(\Rightarrow\)(3) If some minimal left ideal of \( \lambda(X) \) is a (necessarily compact) topological semigroup, then each maximal subgroup of this minimal ideal is a compact topological group.

(3)\(\Rightarrow\)(4) If some maximal subgroup of \( K(\lambda(X)) \) is compact, then by Theorem 18.7(c), each characteristic group \( H(K) \), \( K \in \hat{\mathcal{K}} \), is finite.

(4)\(\Rightarrow\)(1) If each characteristic group \( H(K) \), \( K \in \hat{\mathcal{K}} \), is finite, then Proposition 14.5(1) and Theorem 14.3 guarantee that the semigroup \( \prod_{K \in \hat{\mathcal{K}}} \text{End}^\mathcal{I}(T_K) \) contains a minimal left ideal, which is a topological semigroup. By Corollary 18.6 this minimal left ideal is topologically isomorphic to some minimal left ideal of \( \lambda(X) \).

(4)\(\Rightarrow\)(3) If each characteristic group \( H(K) \), \( K \in \hat{\mathcal{K}} \), is finite, then Theorem 18.7(c) guarantees that each maximal subgroup of \( K(\lambda(X)) \) is a compact topological group.

(3)\(\Rightarrow\)(4) Assume that for some maximal 2-cogroup \( K_\infty \in \hat{\mathcal{K}} \) the characteristic group \( H(K_\infty) \) is infinite. Replacing \( K_\infty \) by a conjugate cogroup, we can assume that \( K_\infty \in \hat{\mathcal{K}} \). By Theorem 8.3, the group \( H(K_\infty) \) is isomorphic to \( C_{2^\infty} \) or \( Q_{2^\infty} \). In both cases, by Theorems 9.5, there is a twin set \( A_\infty \in T_{K_\infty} \) whose characteristic group \( H(A_\infty) \) is not a topological group. Choose a minimal idempotent \( f_{K_\infty} = (f_K)_{K \in \hat{\mathcal{K}}} \in \prod_{K \in \hat{\mathcal{K}}} \text{End}^\mathcal{I}(T_K) \) such that \( f_{K_\infty}(T_{K_\infty}) \subset [A] \). For every \( K \in \hat{\mathcal{K}} \) choose any twin set \( A_K \in f_K(T_K) \) so that \( A_K = A_\infty \) if \( K = K_\infty \).

By Corollary 18.6 there is a minimal idempotent \( \mathcal{E} \in \lambda^\mathcal{I}(X) \) such that \( \Phi_{K_\infty}(\mathcal{E}) = f_{K_\infty} \). By Theorem 18.7(b), the maximal subgroup \( H_K = \lambda(X) \circ \mathcal{E} \circ \lambda(X) \) is topologically isomorphic to \( \prod_{K \in \hat{\mathcal{K}}} H(A_K) \). This subgroup is not a topological group as it contains an isomorphic copy of the right-topological group \( H(A_\infty) \), which is not a topological group.

Now let us write Corollary 18.5 and Theorem 18.7 in a form more convenient for calculations.

For every group \( G \in \{ C_{2^k}, Q_{2^k} : k \in \mathbb{N} \cup \{\infty\} \} \) denote by \( q(X, G) \) the number of orbits \([K] \in [\hat{\mathcal{K}}] \) such that for some (equivalently, every) 2-cogroup \( K \in [K] \) the characteristic group \( H(K) \) is isomorphic to \( G \).
Theorem 18.11. For each twinic group $X$ there is a cardinal $m$ such that

1. each minimal left ideal of $\lambda(X)$ is algebraically isomorphic to the semigroup

$$2^m \times \prod_{1 \leq k \leq \infty} C_{2k}^{q(X,C_{2k})} \times \prod_{3 \leq k \leq \infty} Q_{2k}^{q(X,Q_{2k})},$$

where the Cantor discontinuum $2^m$ is endowed with the left zero multiplication;

2. if $q(X,C_{2\infty}) = q(X,Q_{2\infty}) = 0$ and $\mathcal{H} \cap \hat{K} = \emptyset$, then some minimal left ideal of $\lambda(X)$ is topologically isomorphic to the compact topological semigroup

$$2^m \times \prod_{1 \leq k < \infty} C_{2k}^{q(X,C_{2k})} \times \prod_{3 \leq k < \infty} Q_{2k}^{q(X,Q_{2k})};$$

3. each maximal subgroup of the minimal ideal $K(\lambda(X))$ of $\lambda(X)$ is algebraically isomorphic to the group

$$\prod_{1 \leq k < \infty} C_{2k}^{q(X,C_{2k})} \times \prod_{3 \leq k < \infty} Q_{2k}^{q(X,Q_{2k})},$$

4. if $q(X,C_{2\infty}) = q(X,Q_{2\infty}) = 0$, then each maximal subgroup of the minimal ideal $K(\lambda(X))$ of $\lambda(X)$ is topologically isomorphic to the compact topological group

$$\prod_{1 \leq k < \infty} C_{2k}^{q(X,C_{2k})} \times \prod_{3 \leq k < \infty} Q_{2k}^{q(X,Q_{2k})}.$$

Proof. 1. Fix any $[\hat{K}]$-selection $\hat{K} \subset \hat{K}$. For every $K \in \hat{K}$ put $m_K = |X/K^\pm| = \{K^\pm x : x \in X\}$ if the index of $K$ in $X$ is infinite and $m_K = 2^{|X/K^\pm|}/|H(K)|$ otherwise. It follows that $|T_K| = |T_K/|H(K)| = 2^{m_K}$ and $[T_K]$ is homeomorphic to the Cantor cube $2^{m_K}$ if the characteristic group $H(K)$ is finite. Let $m = \sum_{K \in \hat{K}} m_K$.

By Theorem [18.7], any minimal left ideal $L$ of $\lambda(X)$ is algebraically isomorphic to the semigroup $\prod_{K \in \hat{K}} H(K) \times [T_K]$, where the orbit spaces $[T_K]$ are endowed with the left zero multiplication. By Theorem 8.3, for every $K \in \hat{K}$ the characteristic group $H(K)$ is isomorphic to $C_{2k}$ or $Q_{2k}$ for some $k \in \mathbb{N} \cup \{\infty\}$. According to the definition, for $k \in \{1,2\}$ the group $Q_{2k}$ is isomorphic to the quaternion group $Q_8$. By the definition of $q(X,G)$, for any group $G \in \{C_{2k},Q_{2k} : k \in \mathbb{N} \cup \{\infty\}\}$ we get $q(X,G) = \{K \in \hat{K} : H(K) \cong G\}$ where $\cong$ denotes (semi)group isomorphism.

Now we see that

$$L \cong \prod_{K \in \hat{K}} H(K) \times [T_K] \cong \prod_{K \in \hat{K}} H(K) \times 2^{m_K} \cong \prod_{1 \leq k \leq \infty} C_{2k}^{q(X,C_{2k})} \times \prod_{3 \leq k \leq \infty} Q_{2k}^{q(X,Q_{2k})} \times 2^m.$$

2. If $q(X,C_{2\infty}) = q(X,Q_{2\infty}) = 0$, then for every $K \in \hat{K}$ the characteristic group $H(K)$ is finite and the orbit space $[T_K]$ is a zero-dimensional compact Hausdorff space. In this case $T_K$ is homeomorphic to $[T_K] \times H(K)$. If $K$ has finite index in $X$, then $T_K$ has cardinality $2^{m_K}$ and hence is homeomorphic to the finite cube $2^{m_K}$. If $K$ has infinite index in $X$, then $T_K$ is homeomorphic to $2^{m_K}$ by Proposition [12.1]. It follows from the topological equivalence of $T_K$ and $[T_K] \times H(K)$ that $[T_K]$ is a retract of the Cantor cube $T_K$ and each point of $[T_K]$ has character $m_K$. Now Shchepin’s characterization of Cantor’s cubes [20] implies that the space $[T_K]$ is homeomorphic to the Cantor cube $2^{m_K}$. Then $\prod_{K \in \hat{K}} [T_K]$ is homeomorphic to the Cantor cube $2^m = \prod_{K \in \hat{K}} 2^{m_K}$. 
If \( \mathcal{I} \cap \hat{K} = \emptyset \), then for every \( K \in \hat{K} \) the endomorphism monoid \( \text{End}^{\mathcal{I}}(T_K) \) contains a continuous minimal idempotent \( f_K \) according to Proposition 14.5(1). By Theorem 14.3 the minimal left ideal \( L_{f_K} = \text{End}^{\mathcal{I}}(T_K) \circ f_K \) is topologically isomorphic to the compact topological semigroup \( H(K) \times [T_K] \) where the space \([T_K]\) is endowed with the left zero multiplication. By (the proof of) Corollary 18.6 the minimal idempotent \( K(\lambda(X)) \) contains a maximal linked system \( E \) such that the minimal left ideal \( L_E = \lambda(X) \circ E \) is topologically isomorphic to the minimal left ideal \( \prod_{K \in \hat{K}} L_{f_K} \), which is topologically isomorphic to the compact topological semigroups

\[
\prod_{K \in \hat{K}} H(K) \times [T_K] \quad \text{and} \quad \prod_{1 \leq k < \infty} C_{2^k}^{q(X,C_{2^k})} \times \prod_{3 \leq k < \infty} Q_{2^k}^{q(X,Q_{2^k})} \times 2^m.
\]

3. By Theorem 18.7(b) each maximal subgroup \( H \) of \( K(\lambda(X)) \) is topologically isomorphic to the right-topological group \( G = \prod_{K \in \hat{K}} H(A_K) \) for some twin sets \( A_K \in T_K, K \in \hat{K} \). The latter right-topological group is algebraically isomorphic to the group

\[
\prod_{1 \leq k \leq \infty} C_{2^k}^{q(X,C_{2^k})} \times \prod_{3 \leq k \leq \infty} Q_{2^k}^{q(X,Q_{2^k})}.
\]

4. If \( q(X,C_{2^k}) = q(X,Q_{2^k}) = 0 \), then all characteristic groups \( H(K), K \in \hat{K}, \) are finite and then the group \( G \) is topologically isomorphic to the compact topological group

\[
\prod_{1 \leq k < \infty} C_{2^k}^{q(X,C_{2^k})} \times \prod_{3 \leq k < \infty} Q_{2^k}^{q(X,Q_{2^k})}.
\]

19. The structure of the superextensions of abelian groups

In this section we consider the structure of the superextension of abelian groups. In this case some results of the preceding section can be simplified. In this section we assume that \( X \) is an abelian group. By Theorem 6.2 \( X \) is twinic and has trivial twinic ideal \( \mathcal{I} = \{0\} \). Let us recall that for a group \( G \) we denote by \( q(X,G) \) the number of orbits \([K], K \in \hat{K}\) such that for each \( K \in [K] \) the characteristic group \( H(K) \) is isomorphic to the group \( G \). It is clear that \( q(X,C_{2^k}) = 0 \) for all \( k \in \mathbb{N} \cup \{\infty\} \). On the other hand, the numbers \( q(X,C_{2^k}) \) can be easily calculated using the following proposition.

**Proposition 19.1.** If \( X \) is an abelian group, then for every \( k \in \mathbb{N} \cup \{\infty\} \) the cardinal \( q(X,C_{2^k}) \) is equal to the number of subgroups \( H \subset X \) such that the quotient group \( X/H \) is isomorphic to \( C_{2^k} \). If \( k \in \mathbb{N} \), then

\[
q(X,C_{2^k}) = \frac{|\text{hom}(X,C_{2^k})| - |\text{hom}(X,C_{2^{k-1}})|}{2^{k-1}},
\]

where \( \text{hom}(X,C_{2^k}) \) is the group of all homomorphisms from \( X \) to \( C_{2^k} \).

**Proof.** Since each maximal 2-cogroup \( K \subset X \) is normal, each orbit \([K] \in \hat{K}\) consists of a single maximal 2-cogroup. Consequently, \( q(X,H) \) is equal to the number of maximal 2-cogroups \( K \subset X \) whose characteristic group \( H(K) = \text{Stab}(K)/KK = X/KK \) is isomorphic to \( H \). In other words, \( q(X,H) \) equals to the cardinality of the set

\[
\hat{K}_H = \{K \in \hat{K} : X/KK \cong H\},
\]

where \( \cong \) stands for group isomorphism.
Let \( \mathcal{G}_H \) be the set of all subgroups \( G \subset X \) such that the quotient group \( X/G \) is isomorphic to \( H \). The proposition will be proved as soon as we check that the function 

\[
f: \hat{K}_H \to \mathcal{G}_H, \quad f: K \mapsto KK,
\]

is bijective.

To show that \( f \) is injective, take any two maximal 2-cogroups \( K, C \) with \( KK = f(K) = f(C) = CC \). The quotient group \( X/KK = X/CC \), being isomorphic to \( H \), contains a unique element of order 2. Since \( K \) and \( C \) are cosets of order 2 in \( X/KK = X/CC \), we conclude that \( K = C \).

To show that \( f \) is surjective, take any subgroup \( G \in \mathcal{G}_H \). The quotient group \( X/G \) is isomorphic to \( H \) and thus contains a unique element \( K \) of order 2. This element \( K \) is a maximal 2-cogroup such that \( f(K) = KK = G \).

To prove the second part of the proposition, observe that for a subgroup \( H \subset X \) the quotient group \( X/H \) is algebraically isomorphic to \( C_{2^k} \) if and only if \( H \) coincides with the kernel of some epimorphism \( f: X \to C_{2^k} \). Observe that two epimorphisms \( f, g: X \to C_{2^k} \) have the same kernel if and only if \( g = \alpha \circ f \) for some automorphism \( \alpha \) of the group \( C_{2^k} \). The group \( C_{2^k} \) has exactly \( 2^{k-1} \) automorphisms determined by the image of the generator \( a = e^{i\pi/2^{k+1}} \) of \( C_{2^k} \) in the 2-cogroup \( aC_{2^k-1} \). A homomorphism \( h: X \to C_{2^k} \) is an epimorphism if and only if \( h(X) \not\subset C_{2k-1} \). Consequently, 

\[
q(X, C_{2^k}) = \frac{|\text{hom}(X, C_{2^k}) \setminus \text{hom}(X, C_{2^k-1})|}{2^{k-1}}.
\]

**Theorem 19.2.** If \( X \) is an abelian group, then

1. each maximal subgroup of the minimal ideal \( \mathcal{K}(\lambda(X)) \) is algebraically isomorphic to \( \prod_{1 \leq k \leq \infty} C_{2^k}^{q(X, C_{2^k})} \);  
2. each minimal left ideal of \( \lambda(X) \) is homeomorphic to the Cantor cube \( (2^\omega)^{q(X, C_{2^\omega})} \times \prod_{1 \leq k \leq \infty} (2^{2^{k-1}})^{q(X, C_{2^k})} \) and is algebraically isomorphic to the semigroup \( \prod_{1 \leq k \leq \infty} (C_{2^k} \times Z_k)^{q(X, C_{2^k})} \)

where the cube \( Z_k = 2^{2^{k-1}-k} \) (equal to \( 2^\omega \) if \( k = \infty \)) is endowed with the left zero multiplication;

3. the semigroup \( \lambda(X) \) contains a principal left ideal, which is algebraically isomorphic to the semigroup \( \prod_{1 \leq k \leq \infty} (C_{2^k} \times Z_k^{2^k})^{q(X, C_{2^k})} \).

**Proof.** Since \( X \) is abelian, each 2-cogroup \( K \in \hat{K} \) is normal in \( X \) and hence has one-element orbit \( [K] = \{ xKx^{-1} : x \in X \} \). Then the family \( \hat{K} \) is a unique regular \( \hat{K} \)-selector. Since \( \text{Stab}(K) = X \), the characteristic group \( H(K) = \text{Stab}(X)/KK \) is equal to the quotient group \( X/KK \) and is abelian. By Theorem 8.3, \( H(K) \) is isomorphic to the (quasi)cyclic 2-group \( C_{2^n} \) for some \( n \in \mathbb{N} \cup \{ \infty \} \). Consequently, \( \hat{K} = \bigcup_{1 \leq n \leq \infty} \hat{K}_n \) where \( \hat{K}_n \) is the subset of \( \hat{K} \) that consists of all maximal 2-cogroups \( K \) whose characteristic group \( H(K) = X/KK \) is isomorphic to the group \( C_{2^n} \). By the definition of the numbers \( q(X, G) \), we get \( q(X, C_{2^n}) = |\hat{K}_n| \) for all \( n \in \mathbb{N} \cup \{ \infty \} \).
1. By Theorem 18.7(a), each maximal subgroup of $K(\lambda(X))$ is algebraically isomorphic to $\prod_{K \in \mathcal{K}} H(K)$ and the latter group is isomorphic to
\[
\prod_{1 \leq n \leq \infty} C_{2^n} = \prod_{1 \leq n \leq \infty} C_{q(X,C_{2n})}.
\]

2. By Theorem 18.7(f), each minimal left ideal of $\lambda(X)$ is algebraically isomorphic to $\prod_{K \in \mathcal{K}} (H(K) \times [T_K])$ where the orbit spaces $[T_K]$ are endowed with the left zero multiplication. Let $Z_\infty = 2^\omega$ and $Z_n = 2^{n-1} - n$ for every $n \in \mathbb{N}$. The cubes $Z_n$, $n \in \mathbb{N} \cup \{\infty\}$, are endowed with the left zero multiplication. We claim that $|[T_K]| = |Z_n|$ for each $n \in \mathbb{N} \cup \{\infty\}$. If $n$ is finite, then $|X/K| = \frac{1}{2} |X/KK| = \frac{1}{2} |H(K)| = 2^{n-1}$ and
\[
|[T_K]| = \frac{|T_K|}{|H(K)|} = \frac{2^{X/K}}{2^n} = 2^{2^{n-1} - n} = |Z_n|.
\]
If $n$ is infinite, then the quotient group $H(K) = X/KK$ is isomorphic to $C_{2^\omega}$ and then $|X/K| = \omega$. By Proposition 2.1, the space $T_K$ is homeomorphic to the Cantor cube $2^\omega$ and hence has the cardinality of the continuum. Since the group $H(K)$ is countable, the orbit space $[T_K]$ also has cardinality continuum and hence $|[T_K]| = |2^\omega| = |Z_\infty|$. Now we see that $\prod_{K \in \mathcal{K}} (H(K) \times [T_K])$ is algebraically isomorphic to $\prod_{1 \leq k \leq \infty} (C_{2^k} \times Z_k)^q(X,C_{2^k})$.

3. Since $X$ has trivial twinic ideal, $\mathcal{I} \cap \mathcal{K} = \emptyset$ and by Corollary 18.5(c) and Theorem 14.1(3), the semigroup $\lambda(X)$ contains a principal left ideal that is algebraically isomorphic to the semigroup $\prod_{K \in \mathcal{K}} H(K) \wr [T_K]$, which is algebraically isomorphic to $\prod_{1 \leq k \leq \infty} (C_{2^k} \wr Z_k)^q(X,C_{2^k})$.

The following theorem characterizes the groups $X$ for which the algebraic isomorphism in Theorem 19.2 are topological.

**Theorem 19.3.** For an abelian group $X$ the following conditions are equivalent:

1. the group $X$ admits no homomorphism onto the quasicyclic 2-group $C_{2^\omega}$;
2. each maximal subgroup in the minimal ideal $K(\lambda(X))$ of $\lambda(X)$ is topologically isomorphic to the compact topological group $\prod_{k \in \mathbb{N}} C_{2^k}^{q(X,C_{2^k})}$;
3. each maximal subgroup in $K(\lambda(X))$ is a topological group;
4. some maximal subgroup of $K(\lambda(X))$ is compact;
5. each minimal left ideal of $\lambda(X)$ is topologically isomorphic to the compact topological semigroup
\[
\prod_{k \in \mathbb{N}} (C_{2^k} \times Z_k)^q(X,C_{2^k})
\]
where the finite cube $Z_k = 2^{2^k - 1} - k$ is endowed with the left zero multiplication;
6. $\lambda(X)$ contains a principal left ideal which is topologically isomorphic to the compact topological semigroup
\[
\prod_{k \in \mathbb{N}} (C_{2^k} \wr Z_k^q(X,C_{2^k})
\]

**Proof.** Let the subfamilies $\mathcal{K}_n \subset \mathcal{K}$ and the Cantor cubes $Z_n = 2^{2^{n-1} - n}$, $n \in \mathbb{N} \cup \{\infty\}$, be defined as in the proof of Theorem 19.2. Then $q(X,C_{2^n}) = |\mathcal{K}_n|$. 

(1)⇒(5, 6) If \( X \) admits no homomorphism onto \( C_{2^\infty} \), then \( q(X, C_{2^\infty}) = 0 \) and \( \hat{\mathcal{C}}_\infty = \emptyset \). In this case \( \hat{\mathcal{C}} = \bigcup_{n \in \mathbb{N}} \hat{\mathcal{C}}_n \). For every \( n \in \mathbb{N} \) and \( K \in \hat{\mathcal{C}}_n \) the characteristic group \( H(K) \) is isomorphic to \( C_{2^n} \) and the orbit space \( |T_K| \) is homeomorphic to the cube \( Z_k \). By Theorem [14.1(3)], the monoid \( \text{End}(T_K) \) is (topologically) isomorphic to \( H(K) \wr |T_K|^{T_K} \) and the latter semigroup is topologically isomorphic to \( C_{2^n} \wr Z_n^{Z^n} \).

By Theorem [18.7(g)], each minimal left ideal of \( \lambda(X) \) is topologically isomorphic to

\[
\prod_{K \in \hat{\mathcal{C}}} H(K) \times |T_K| = \prod_{n \in \mathbb{N}} \prod_{K \in \hat{\mathcal{C}}_n} H(K) \times |T_K|
\]

and the latter semigroup is topologically isomorphic to the compact topological semigroup

\[
\prod_{k \in \mathbb{N}} (C_{2^k} \times Z_k)^{|q(X, C_{2^k})|}.
\]

By Corollary [18.5(3)] and Theorem [14.1(3)], the semigroup \( \lambda(X) \) contains a principal left ideal that is topologically isomorphic to the compact topological semigroup

\[
\prod_{K \in \hat{\mathcal{C}}} H(K) \wr |T_K|^{T_K} = \prod_{n \in \mathbb{N}} \prod_{K \in \hat{\mathcal{C}}_n} H(K) \wr |T_K|^{T_K},
\]

which is topologically isomorphic to the compact topological semigroup

\[
\prod_{k \in \mathbb{N}} (C_{2^k} \wr Z_k^{|q(X, C_{2^k})|}).
\]

The implications (5)⇒(2)⇒(3) are trivial.

(3)⇒(1) If the group \( X \) admits a homomorphism onto \( C_{2^\infty} \), then the family \( \hat{\mathcal{C}} \) contains a 2-cogroup \( K_\infty \) whose characteristic group \( H(K_\infty) \) is isomorphic to \( C_{2^\infty} \). It follows from Example [9.3(2)] that for some twin set \( A_{K_\infty} \in T_{K_\infty} \) the twin-generated group \( H(A_{K_\infty}) \) is not a topological group. Now choose a sequence \( (A_K)_{K \in \hat{\mathcal{C}}} \subseteq \prod_{K \in \hat{\mathcal{C}}} T_K \) of twin sets such that \( A_K = A_{K_\infty} \) if \( K = K_\infty \). Then the right-topological group \( \prod_{K \in \hat{\mathcal{C}}} H(A_K) \) is not a topological group. By Corollary [18.6] this right-topological group is topologically isomorphic to some maximal subgroup of the minimal ideal \( K(\lambda(X)) \). So, \( K(\lambda(X)) \) contains a maximal subgroup which is not a topological group.

(6)⇒(4) If \( \lambda(X) \) contains a left ideal which is a topological semigroup, then \( \lambda(X) \) contains a minimal left ideal which is a topological semigroup. Any maximal subgroup of this minimal left ideal is a compact topological group.

(4)⇒(1) If \( K(\lambda(X)) \) contains a compact maximal subgroup, then by Theorem [18.7(c)], each characteristic group \( H(K) \), \( K \in \hat{\mathcal{C}} \), is finite and hence \( q(X, C_{2^\infty}) = 0 \).

Finally, we shall characterize abelian groups whose superextension contains metrizable minimal left ideals. The characterization involves the notions of free rank and 2-rank (see [11 §16] or [19 §4.2]).

Let us recall that a subset \( A \neq e \) of an abelian group \( G \) with neutral element \( e \) is called independent if for any disjoint subsets \( B, C \subseteq A \) the subgroups \( \langle B \rangle \) and \( \langle C \rangle \) generated by \( B, C \) intersect in the trivial subgroup. The cardinality of a maximal independent subset \( A \subseteq G \) that consists of elements of infinite order (resp. of order that is a power of 2) is called the free rank (resp. the 2-rank) of \( G \) and is denoted by \( r_0(G) \) (resp. \( r_2(G) \)).
THEOREM 19.4. For an abelian group $X$ the following conditions are equivalent:

1. each minimal left ideal of $\lambda(X)$ is metrizable;
2. the family $\hat{K}$ of maximal 2-cogroups is at most countable;
3. the group $X$ admits no epimorphism onto the group $C_2^\omega \oplus C_2^\omega$ and $X$ has finite ranks $r_0(X)$ and $r_2(X)$.

Proof. (1)$\iff$(2) By Theorem 19.2(2), each minimal left ideal is homeomorphic to the cube $$(2^\omega)^{\varphi(X,C_2^\omega)} \times \prod_{1 \leq k < \infty} (2^{2^k-1})^{\varphi(X,C_2^k)},$$ which is metrizable if and only if $|\hat{K}| = \sum_{1 \leq k \leq \infty} \varphi(X,C_2^k) \leq \aleph_0$.

For the proof of the equivalence (2)$\iff$(3) we need two lemmas. We define a group $G$ to be $\hat{K}$-countable if the family of maximal 2-cogroups in $G$ is at most countable.

LEMMA 19.5. Each subgroup and each quotient group of a $\hat{K}$-countable group is $\hat{K}$-countable.

Proof. Assume that a group $G$ is $\hat{K}$-countable. To prove that any subgroup $H \subset G$ is $\hat{K}$-countable, observe that by Proposition 7.3(2), each 2-cogroup $K \subset H$ can be enlarged to a maximal 2-cogroup $\hat{K}$ in $G$. The maximality of $K$ in $H$ guarantees that $K = \hat{K} \cap H$. This implies that the number of maximal 2-cogroups in $H$ does not exceed the number of maximal 2-cogroups in $G$.

To prove that any quotient group $G/H$ of $G$ by a normal subgroup $H \subset G$ is $\hat{K}$-countable, observe that for each maximal 2-cogroup $K \subset G/H$ the preimage $q^{-1}(K)$ under the quotient homomorphism $q : G \to G/H$ is a maximal 2-cogroup in $G$. This implies that the number of maximal 2-cogroups in $G/H$ does not exceed the number of maximal 2-cogroups of $G$.

For a group $G$ with neutral element $e$ and a set $A$ we denote by $$\oplus^A G = \{(x_\alpha)_{\alpha \in A} \in G^A : |\{\alpha \in A : x_\alpha \neq e\}| < \aleph_0\}$$ the direct sum of $|A|$ many copies of $G$.

LEMMA 19.6. The groups $\oplus^\omega C_2$, $\oplus^\omega \mathbb{Z}$ and $C_2^\omega \times C_2^\omega$ are not $\hat{K}$-countable.

Proof. Observe that for any abelian group $X$ the number $q(X,C_2)$ is equal to the number of subgroups having index 2 and is equal to the number of non-trivial homomorphisms $h : X \to C_2$.

Each (non-empty) subset $A \subset \omega$ determines a (non-trivial) homomorphism $$h_A : \oplus^\omega C_2 \to C_2, \quad h_A : (x_i)_{i \in \omega} \mapsto \prod_{i \in A} x_i.$$ For any distinct subsets $A, B \subset \omega$ the homomorphisms $h_A$ and $h_B$ are distinct. Consequently, for the group $X = \oplus^\omega C_2$, the family $\hat{K}$ of maximal 2-cogroups has cardinality $|\hat{K}| \geq \text{hom}(X,C_2) = 2^\omega$ and hence this group is not $\hat{K}$-countable.

Since $\oplus^\omega C_2$ is a quotient group of $\oplus^\omega \mathbb{Z}$, the latter group is not $\hat{K}$-countable.

Finally, we show that $X = C_2^\omega \times C_2^\omega$ is not $\hat{K}$-countable. It is well-known (see [7 §43]) that the quasicyclic group $C_2^\omega$ has uncountable automorphism group $\text{Aut}(C_2^\omega)$. 

For any automorphism \( h : C_{2^\infty} \to C_{2^\infty} \) its graph \( \Gamma_h = \{(x, h(x)) : x \in C_{2^\infty}\} \) is a subgroup of \( X = C_{2^\infty} \times C_{2^\infty} \) such that the quotient group \( X/\Gamma_h \) is isomorphic to \( C_{2^\infty} \). Consequently, \( q(X, C_{2^\infty}) \geq \text{Auth}(C_{2^\infty}) > \aleph_0 \) and hence \( X \) is not \( \hat{\mathcal{K}} \)-countable. □

Now we are able to prove the equivalence \((2) \iff (3)\) of Theorem \[19.4\]. The implication \((2) \Rightarrow (3)\) follows from Lemmas \[19.5\] and \[19.6\].

To prove the implication \((3) \Rightarrow (2)\), assume that an abelian group \( X \) has finite free rank and 2-rank, and \( X \) admits no homomorphism onto the group \( C_{2^\infty} \oplus C_{2^\infty} \). By Proposition \[19.1\], the cardinality of the set \( \hat{\mathcal{K}} \) of maximal 2-cogroups in \( X \) is equal to the cardinality of the family \( \mathcal{H} \) of subgroups \( H \subset X \) such that the quotient group \( X/H \) is isomorphic to \( C_{2^k} \) for some \( 1 \leq k \leq \infty \). So, it suffices to prove that \(|\mathcal{H}| \leq \aleph_0\).

Consider the subgroup \( X_{\text{odd}} \subset X \) consisting of the elements of odd order. Since \( X \) has finite free rank and 2-rank, so does the quotient group \( X/X_{\text{odd}} \). The quotient group \( Y = X/X_{\text{odd}} \) is at most countable (because it contains no elements of odd order and has finite free rank and 2-rank). Let \( q : X \to Y \) be the quotient homomorphism.

Let \( \mathcal{M} \) be the family of maximal independent subsets consisting of elements of infinite order in the group \( Y = X/X_{\text{odd}} \). Since the free rank of \( Y \) is finite, each (independent) set \( M \in \mathcal{M} \) is finite and hence \( \mathcal{M} \) is at most countable.

For each \( M \in \mathcal{M} \) consider the free abelian subgroup \( \langle M \rangle \subset Y \) generated by \( M \). Let \( G_M = Y/\langle M \rangle \) be the quotient group and \( q_M : Y \to G_M \) be the quotient homomorphism. The maximality of \( M \) implies that \( G_M \) is a torsion group. Since the free rank and the 2-rank of \( Y \) are finite, \( G_M \) has finite 2-rank. The group \( G_M \) is the direct sum \( G_M = O_M \oplus D_M \) of the subgroup \( O_M \) of elements of odd order and the maximal 2-subgroup \( D_M \subset G_M \). Let \( p_M : G_M \to D_M = G_M/O_M \) be the quotient homomorphism.

We claim that the group \( D_M \) has at most countably many subgroups. Since \( D_M \) is a quotient group of \( X \) and \( X \) admits no homomorphism onto the group \( C_{2^\infty} \), the group \( D_M \) also admits no homomorphism onto \( C_{2^\infty} \). Two cases are possible.

1) The group \( D_M \) contains no subgroup isomorphic to \( C_{2^\infty} \). In this case Prüfer’s Theorem 17.2 of \[7\] guarantees that \( D_M \) is a direct sum of cyclic 2-groups. Since \( D_M \) has finite 2-rank, it is finite, being a finite sum of cyclic 2-groups. Thus \( D_M \) has finitely many subgroups.

2) The group \( D_M \) contains a subgroup \( D \subset M \) isomorphic to \( C_{2^\infty} \). Being divisible, the subgroup \( D \) is complemented in \( D_M \), which means that \( D_M = D \oplus F \) for some subgroup \( F \subset D_M \). Since \( D_M \) admits no homomorphism onto \( C_{2^\infty} \), the subgroup \( F \) contains no subgroup isomorphic to \( C_{2^\infty} \) and hence is finite by the preceding case. Taking into account that the quasicyclic 2-group \( D \) has countably many subgroups, we conclude that the group \( D_M = D \oplus F \) also has countably many subgroups.

In both cases the family \( \mathcal{D}_M \) of subgroups of \( D_M \) is at most countable. Then the family \( \mathcal{H}_M = \{(p_M \circ q_M \circ q)^{-1}(H) : H \in \mathcal{D}_M\} \) is also at most countable. It remains to check that \( \mathcal{H} \subset \bigcup_{M \in \mathcal{M}} \mathcal{H}_M \).

Fix any subgroup \( H \in \mathcal{H} \). By the definition of \( \mathcal{H} \), the quotient group \( X/H \) is a 2-group, which implies \( X_{\text{odd}} \subset H \). Then \( H = q^{-1}(H_Y) \) where \( H_Y = q(H) \). Let \( M \) be a maximal independent subset of \( H_Y \) that consists of elements of infinite order. Since \( Y/H_Y = X/H \) is a torsion group, the set \( M \) is maximal in \( Y \) and hence belongs to \( \mathcal{M} \). It
follows that $\langle M \rangle \subset H_Y$ and hence $H_Y = q_{M}^{-1}(H_M)$ where $H_M = q_{M}(H_Y) \subset G_M$. Since $G_M/H_M = Y/H_Y = X/H$ is a 2-group, the subgroup $H_M$ contains the subgroup $O_M$ of elements of odd order in $G_M$. Then $H_M = p_{M}^{-1}(G_M)$ where $G_M = p_{M}(H_M) \subset D_M$. Since $G_M \in D_M$, the group $H = (p_{M} \circ q_{M} \circ q)^{-1}(G_M)$ belongs to the family $\mathcal{H}_{M} \subset \mathcal{H}$.

20. Compact reflexions of groups

In this section $X$ is an arbitrary group. Till this moment our strategy in describing the minimal left ideals of the semigroups $\lambda(X)$ consisted in finding a relatively small subfamily $F \subset P(X)$ such that the function representation $\Phi_{F} : \lambda(X) \to \text{End}_{\lambda}(F)$ is injective on all minimal left ideals of $\lambda(X)$. Now we shall simplify the group $X$ keeping the minimal left ideals of $\lambda(X)$ unchanged.

We shall describe three such simplifying procedures. One of them is the factorization of $X$ by the subgroup

$$\text{Odd} = \bigcap_{K \in \mathcal{K}} KK.$$ 

Here we assume that $\text{Odd} = X$ if the set $\mathcal{K}$ is empty.

The following proposition explains the choice of the notation for the subgroup $\text{Odd}$. We recall that a group $G$ is called odd if each element of $G$ has odd order.

**Proposition 20.1.** Odd is the largest normal odd subgroup of $X$. If $X$ is abelian, then Odd coincides with the set of all elements having odd order in $X$.

**Proof.** The normality of the subgroup $\text{Odd} = \bigcap_{K \in \mathcal{K}} KK$ follows from the fact that $xKx^{-1} \in \mathcal{K}$ for every $K \in \mathcal{K}$ and $x \in X$. Next, we show that the group Odd is odd. Assuming the contrary, we could find an element $a \in \text{Odd}$ such that the sets $a^{2^n} = \{a^{2^n} : n \in \mathbb{Z}\}$ and $a^{2^{n+1}} = \{a^{2^{n+1}} : n \in \mathbb{Z}\}$ are disjoint. Then the 2-cogroup $a^{2^{n+1}}$ of $X$ can be enlarged to a maximal 2-cogroup $K \in \mathcal{K}$. It follows that $a \in K \subset X \setminus KK$ and thus $a \notin \text{Odd}$, which is a contradiction.

It remains to prove that Odd contains any normal odd subgroup $H \subset X$. It suffices to check that for every maximal 2-cogroup $K \in \mathcal{K}$ the subgroup $H \subset X$ lies in the group $KK$. Let $K^\pm = K \cup KK$. Since the subgroup $H$ is normal in $X$, the sets $KKH = HKK$ and $K^\pm H = HKK^\pm$ are subgroups. We claim that the sets $KH = HK$ and $KKH = HKK$ are disjoint. Assuming that $KH \cap KKH \neq \emptyset$, we can find $x \in K$ such that $x \in KKH$. Since $KK = xK$, there are $z \in K$ and $h \in H$ such that $x = xzh$. Then $z = h^{-1} \in K \cap H$. Now consider the cyclic subgroup $z^{2^n} = \{z^{2^n} : n \in \mathbb{Z}\}$. Since $z \in K$, the subgroup $z^{2^n}$ does not intersect the set $z^{2^{n+1}} = \{z^{2^{n+1}} : n \in \mathbb{Z}\}$. On the other hand, since $H$ is odd, there is an $n \in \mathbb{Z}$ with $z^{2^{n+1}} = z^0 \in z^{2^{n+1}} \cap z^{2^n}$. This contradiction shows that $KH$ and $KKH$ are disjoint. Consequently, the subgroup $KKH$ has index 2 in the group $K^\pm H$ and hence $KH = K^\pm H \setminus KKH$ is a 2-cogroup in $X$ containing $H$. The maximality of $K$ in $\mathcal{K}$ guarantees that $K = KH$ and hence $H \subset KK$.

The quotient homomorphism $q_{\text{Odd}} : X \to X/\text{Odd}$ generates a continuous semigroup homomorphism $\lambda(q_{\text{Odd}}) : \lambda(X) \to \lambda(X/\text{Odd})$. 

\[ T. \text{Banakh and V. Gavrylkiv} \]
The following theorem was proved in [3, 3.3].

**Theorem 20.2.** The homomorphism $\lambda(q_{\text{odd}}) : \lambda(X) \to \lambda(X/\text{Odd})$ is injective on each minimal left ideal of $\lambda(X)$.

Next, we define two compact topological groups called the first and second profinite reflexions of the group $X$. To define the first profinite reflexion, consider the family $\mathcal{N}$ of all normal subgroups of $X$ with finite index in $X$. For each subgroup $H \in \mathcal{N}$ consider the quotient homomorphism $q_H : X \to X/H$. The diagonal product of those homomorphisms determines the homomorphism $q : X \to \prod_{H \in \mathcal{N}} X/H$ of $X$ into the compact topological group $\prod_{H \in \mathcal{N}} X/H$. The closure of the image $q(X)$ in $\prod_{H \in \mathcal{N}} X/H$ is denoted by $\bar{X}$ and is called the *profinite reflexion* of $X$.

The second profinite reflexion $\bar{X}_2$ is defined in a similar way using the subfamily

$$\mathcal{N}_2 = \left\{ \bigcap_{x \in X} xKx^{-1} : K \in \hat{\mathcal{K}}, |X/K| < \aleph_0 \right\}$$

of $\mathcal{N}$. The quotient homomorphisms $q_H : X \to X/H$, $H \in \mathcal{N}_2$, compose a homomorphism $q_2 : X \to \prod_{H \in \mathcal{N}_2} X/H$. The closure of the image $q_2(X)$ in $\prod_{H \in \mathcal{N}_2} X/H$ is denoted by $\bar{X}_2$ and is called the *second profinite reflexion* of $X$. Since $\text{Ker}(q_2) = \bigcap \mathcal{N}_2 \supset \bigcap_{K \in \hat{\mathcal{K}}} K \supset \text{Odd}$, the homomorphism $q_2 : X \to \bar{X}_2$ factorizes through the group $X/\text{Odd}$ in the sense that there is a unique homomorphism $q_{\text{even}} : X/\text{Odd} \to \bar{X}_2$ such that $q_2 = q_{\text{even}} \circ q_{\text{odd}}$.

Thus we get the following commutative diagram:

\[
\begin{array}{ccc}
X & \xrightarrow{q_{\text{odd}}} & X/\text{Odd} \\
\downarrow q & \downarrow & \downarrow q_{\text{even}} \\
\bar{X} & \xrightarrow{\text{pr}} & \bar{X}_2
\end{array}
\]

Applying to this diagram the functor $\lambda$ of superextension we get the diagram

\[
\begin{array}{ccc}
\lambda(X) & \xrightarrow{\lambda(q_{\text{odd}})} & \lambda(X/\text{Odd}) \\
\downarrow \lambda&q & \downarrow \lambda(q_{\text{even}}) \\
\lambda(\bar{X}) & \xrightarrow{\lambda(\text{pr})} & \lambda(\bar{X}_2)
\end{array}
\]

In this diagram $\lambda(\bar{X})$ and $\lambda(\bar{X}_2)$ are the superextensions of the compact topological groups $\bar{X}$ and $\bar{X}_2$. We recall that the superextension $\lambda(K)$ of a compact Hausdorff space $K$ is the closed subspace of the second exponent exp(exp($K$)) that consists of the maximal linked systems of closed subsets of $K$ (see [22, §2.1.3]).

**Theorem 20.3.** If each maximal 2-cogroup $K$ of a twinic group $X$ has finite index in $X$, then the homomorphism $\lambda(q_2) : \lambda(X) \to \lambda(\bar{X}_2)$ is injective on each minimal left ideal of $\lambda(X)$.

**Proof.** The injectivity of the homomorphism $\lambda(q_2)$ on a minimal left ideal $L$ of $\lambda(X)$ will follow as soon as for any distinct maximal linked systems $A, B \in L$ we find a subgroup $H \in \mathcal{N}_2$ such that $\lambda q_H(A) \neq \lambda q_H(B)$. Fix any $[\hat{\mathcal{K}}]$-selector $\hat{\mathcal{K}} \subset \hat{\mathcal{K}}$. 
By Corollary 18.5, the homomorphism \( \Phi_T : \lambda(X) \to \prod_{K \in \mathcal{K}} \text{End}_\lambda(T_K) \), \( \Phi_T : \mathcal{L} \mapsto (\Phi_L|T_K)_{K \in \mathcal{K}} \), is injective on the minimal left ideal \( \mathcal{L} \). Consequently, \( \Phi_A|T_K \neq \Phi_B|T_K \) for some \( K \in \mathcal{K} \) and we can find a set \( T \in T_K \) such that \( \Phi_A(T) \neq \Phi_B(T) \).

Since the 2-cogroup \( K \) has finite index in \( X \), the normal subgroup \( H = \bigcap_{x \in X} xKEx^{-1} \) has finite index in \( X \) and belongs to the family \( \mathcal{N}_2 \). Consider the finite quotient group \( X/H \) and let \( q_H : X \to X/H \) be the quotient homomorphism. Since \( H \subset KK \), the set \( T = KKT \) coincides with the preimage \( q_H^{-1}(T') \) of some twin set \( T' \in X/H \). This fact can be used to show that \( \lambda q_H(A) \neq \lambda q_H(B) \). □

**Remark 20.4.** For each finite abelian group \( X \) the group \( X/\text{Odd} \) is a 2-group. For non-commutative groups this is not always true: for the group \( X = A_4 \) of even permutations of the set \( 4 = \{0, 1, 2, 3\} \) the group \( X/\text{Odd} \) coincides with \( X \) (see Section 21.5). Also \( X/\text{Odd} \) coincides with \( X \) for any simple group.

## 21. Some examples

Now we consider the superextensions of some concrete groups.

### 21.1. The infinite cyclic group \( \mathbb{Z} \)

In order to compare the algebraic properties of the semigroups \( \lambda(\mathbb{Z}) \) and \( \beta(\mathbb{Z}) \) let us recall a deep result of E. Zelenyuk [23] (see also [12, §7.1]) who proved that each finite subgroup in the subsemigroup \( \beta(\mathbb{Z}) \subset \lambda(\mathbb{Z}) \) is trivial. It turns out that the semigroup \( \lambda(\mathbb{Z}) \) has a totally different property.

**Theorem 21.1.**

1. The semigroup \( \lambda(\mathbb{Z}) \) contains a principal left ideal topologically isomorphic to \( \prod_{k=1}^{\infty} C_{2^k} \times Z_k^{2^k-1} \) where \( Z_k = 2^{2^{k-1}-1} \).
2. Each minimal left ideal of \( \lambda(\mathbb{Z}) \) is topologically isomorphic to \( 2^\omega \times \prod_{k=1}^{\infty} C_{2^k} \) where the Cantor cube \( 2^\omega \) is endowed with the left zero multiplication.
3. Each maximal group of the minimal ideal \( \mathcal{K}(\lambda(\mathbb{Z})) \) is topologically isomorphic to \( \prod_{k=1}^{\infty} C_{2^k} \).
4. The semigroup \( \lambda(\mathbb{Z}) \) contains a topologically isomorphic copy of each second countable profinite topological semigroup.

**Proof.** The group \( \mathbb{Z} \) is abelian and hence has trivial twinic ideal according to Theorem 6.2.

It is easy to see that \( q(\mathbb{Z}, C_{2^k}) = 1 \) for all \( k \in \mathbb{N} \), while \( q(\mathbb{Z}, C_{2^\omega}) = 0 \).

1. By Theorem 19.3(6), the semigroup \( \lambda(\mathbb{Z}) \) contains a principal left ideal that is topologically isomorphic to \( \prod_{k=1}^{\infty} C_{2^k} \times Z_k^{2^k-1} \) where \( Z_k = 2^{2^{k-1}-1} \).

2. By Theorem 19.3(5), each minimal left ideal \( L \) of \( \lambda(\mathbb{Z}) \) is topologically isomorphic to \( \prod_{k=1}^{\infty} C_{2^k} \times Z_k \) where each cube \( Z_k = 2^{2^{k-1}-1} \) is endowed with the left zero multiplication. It is easy to see that the left zero semigroup \( \prod_{k=1}^{\infty} Z_k \) is topologically isomorphic to the Cantor cube \( 2^\omega \) endowed with the left zero multiplication. Consequently, \( L \) is topologically isomorphic to \( 2^\omega \times \prod_{k=1}^{\infty} C_{2^k} \).

3. The preceding item implies that each maximal group of the minimal ideal \( \mathcal{K}(\lambda(\mathbb{Z})) \) is topologically isomorphic to \( \prod_{k=1}^{\infty} C_{2^k} \).
4. The fourth item follows from the first item and the following well-known fact (see [I.1.3]).

**Lemma 21.2.** Each semigroup $S$ is algebraically isomorphic to a subsemigroup of the semigroup $A^A$ of all self-maps of a set $A$ of cardinality $|A| \geq |S^1|$ where $S^1$ is $S$ with attached unit.

21.2. The (quasi)cyclic 2-groups $C_{2^n}$. For a cyclic 2-group $X = C_{2^n}$,

$$q(X, C_{2^k}) = \begin{cases} 1 & \text{if } k \leq n, \\ 0 & \text{otherwise.} \end{cases}$$

Applying Theorem 19.3 we get:

**Theorem 21.3.** For every $n \in \mathbb{N}$,

1. the semigroup $\lambda(C_{2^n})$ contains a principal left ideal isomorphic to $\prod_{k=1}^{n} C_{2^k} \wr Z_{k}^{Z_k}$ where $Z_k = 2^{2^{k-1} - k}$;
2. each minimal left ideal of $\lambda(C_{2^n})$ is isomorphic to $\prod_{k=1}^{n} C_{2^k} \times Z_k$ where each cube $Z_k = 2^{2^{k-1} - k}$ is endowed with the left zero multiplication;
3. each maximal group of the minimal ideal $\mathcal{K}(\lambda(C_{2^n}))$ is isomorphic to $\prod_{k=1}^{n} C_{2^k}$;
4. the semigroup $\lambda(C_{2^n})$ contains an isomorphic copy of each semigroup $S$ of cardinality $|S| < 2^{2^{n-1} - n}$.

The superextension $\lambda(C_{2^\infty})$ has even more interesting properties.

**Theorem 21.4.**

1. Minimal left ideals of the semigroup $\lambda(C_{2^\infty})$ are not topological semigroups.
2. Each minimal left ideal of $\lambda(C_{2^\infty})$ is homeomorphic to the Cantor cube $2^\omega$ and is algebraically isomorphic to $\varepsilon \times (C_{2^\infty})^\omega$ where the cardinal $\varepsilon = 2^{\aleph_0}$ is endowed with the left zero multiplication.
3. The semigroup $\lambda(C_{2^\infty})$ contains a principal left ideal which is algebraically isomorphic to $(C_{2^\infty} \wr \varepsilon)^\omega$.
4. $\lambda(C_{2^\infty})$ contains an isomorphic copy of each semigroup of cardinality $\leq \varepsilon$.
5. Each maximal subgroup of the minimal ideal $\mathcal{K}(\lambda(C_{2^\infty}))$ of $\lambda(C_{2^\infty})$ is algebraically isomorphic to $(C_{2^\infty})^\omega$.
6. Each maximal subgroup of the minimal ideal $\mathcal{K}(\lambda(C_{2^\infty}))$ is topologically isomorphic to the countable product $\prod_{n=1}^{\infty} (C_{2^\infty}, \tau_n)$ of quasicyclic 2-groups endowed with twin-generated topologies.
7. For any twin-generated topologies $\tau_n$, $n \in \mathbb{N}$, on $C_{2^\infty}$ the right-topological group $\prod_{n=1}^{\infty} (C_{2^\infty}, \tau_n)$ is topologically isomorphic to a maximal subgroup of $\mathcal{K}(\lambda(C_{2^\infty}))$.

**Proof.** Since each proper subgroup of $C_{2^\infty}$ is finite, the family $\hat{\mathcal{K}}$ of maximal 2-cogroups is countable and hence can be enumerated as $\hat{\mathcal{K}} = \{ K_n : n \in \omega \}$. Each maximal 2-cogroup $K \in \hat{\mathcal{K}}$ has infinite index and its characteristic group $\mathcal{H}(K)$ is isomorphic to $C_{2^\infty}$.

1. The equivalence $\Rightarrow$ of Theorem 19.3 implies that no minimal left ideal of $\lambda(C_{2^\infty})$ is a topological semigroup.
2, 3, 5. The statements (2), (3) and (5) follow from Theorem 19.2.
4. The fourth item follows from the third one because each semigroup $S$ of cardinality $|S| \leq c$ embeds into the semigroup $c^3$ according to Lemma 21.2.

6. By Theorem 18.7(b), each maximal subgroup $G$ in the minimal ideal $K(\lambda(C_{2^\infty}))$ is topologically isomorphic to the product $\prod_{K \in \mathcal{K}} H(A_K)$ of the structure groups of suitable twin subsets $A_K \in T_K = T[K], \ K \in \mathcal{K}$. For each maximal 2-cogroup $K \in \mathcal{K}$ the structure group $H(A_K)$ is just $C_{2^\infty}$ endowed with a twin-generated topology.

7. Now assume conversely that $\tau_n, \ n \in \mathbb{N}$, are twin-generated topologies on the quasicyclic group $C_{2^\infty}$. For every $n \in \mathbb{N}$ find a twin subset $A_n \in T_{K_n}$ whose structure group $H(A_n)$ is topologically isomorphic to $(C_{2^\infty}, \tau_n)$. By Theorem 18.8 the product $\prod_{n=1}^{\infty} H(A_n)$ is topologically isomorphic to some maximal subgroup of $K(\lambda(C_{2^\infty}))$.

Remark 21.5. Theorems 21.4(7) and 9.5 imply that among maximal subgroups of the minimal ideal of $\lambda(C_{2^\infty})$ are:

- Raikov complete topological groups;
- incomplete totally bounded topological groups;
- paratopological groups which are not topological groups;
- semitopological groups which are not paratopological groups.

21.3. The groups $Q_{2^n}$ of generalized quaternions. We start with the quaternion group $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$. It contains three cyclic subgroups of order 4 corresponding to 4-element maximal 2-cogroups: $K_1 = Q_8 \setminus \langle i \rangle$, $K_2 = Q_8 \setminus \langle j \rangle$, $K_3 = Q_8 \setminus \langle k \rangle$. The characteristic groups of those 2-cogroups are isomorphic to $C_2$. The trivial subgroup of $Q_8$ corresponds to the maximal 2-cogroup $K_0 = \{1\}$ whose characteristic group coincides with $Q_8$. By Proposition 14.2 we get

$$||T_{K_0}|| = \frac{|T_{K_0}|}{|H(K_0)|} = \frac{2^{|X/K_0^\pm|}}{|Q_8|} = 2$$

and $||T_{K_i}|| = 1$ for $i \in \{1, 2, 3\}$. By Theorem 18.7(2), each minimal left ideal of the semigroup $\lambda(Q_8)$ is isomorphic to

$$(Q_8 \times 2) \times (C_2 \times 1)^3 = 2 \times Q_8 \times C_2^3.$$
It is easy to check that two 2-cogroups $K_{k,x}$ and $K_{k,y}$ are conjugate if and only if $xy^{-1} \in C_{2n-1}$. Taking any elements $x, y \in Q_{2n+1} \setminus C_{2n}$ with $xy^{-1} \notin C_{2n}$, we conclude that the family

$\tilde{K} = \{K_0, K_{k,x}, K_{k,y} : 2 \leq k \leq n\}$

is a $[\tilde{K}]$-selector. Applying Theorems 18.7, 14.1(3) and Corollary 18.5(3), we get:

**Theorem 21.6.** Let $n \geq 2$ be a finite number. Then

1. each minimal left ideal of the semigroup $\lambda(Q_{2n+1})$ is isomorphic to

   $$Q_{2n+1} \times 2^{2n-n-1} \times C_2 \times \prod_{k=2}^{n} (C_2 \times 2^{2n-k-1}),$$

   where the cubes $2^{2n-n-1}$ and $2^{2n-k-1}$ are endowed with the left zero multiplication;

2. each maximal subgroup of the minimal ideal $K(\lambda(Q_{2n+1}))$ is isomorphic to $Q_{2n+1} \times C_{2^{2n-1}}$.

The infinite group $Q_{2\infty}$ of generalized quaternions has a similar structure. This group contains the following maximal 2-cogroups:

$$K_0 = \{−1\}, \quad K_1 = Q_{2\infty} \setminus C_{2\infty}, \quad \text{and} \quad K_{k,x} = \{1, x\} \cdot C_{2k} \setminus C_{2k−1}$$

where $k \geq 2$ and $x \in Q_{2\infty} \setminus C_{2\infty}$. For these 2-cogroups we get

$$H(K_0) = Q_{2\infty}, \quad H(K_1) = C_2, \quad \text{and} \quad H(K_{k,x}) = C_2$$

and

$$||T_{K_0}|| = c, \quad ||T_{K_1}|| = 1, \quad \text{and} \quad ||T_{K_{k,x}}|| = c.$$

Any two 2-cogroups $K_{k,x}$, $K_{k,y}$ are conjugate. Then for any $b \in Q_{2\infty} \setminus C_{2\infty}$ the family $\tilde{K} = \{K_0, K_{k,b} : k \in \mathbb{N}\}$ is a $[\tilde{K}]$-selector. By analogy with Theorem 21.4 we can prove:

**Theorem 21.7.** For the group $Q_{2\infty}$,

1. minimal left ideals of the semigroup $\lambda(C_{2\infty})$ are not topological semigroups;

2. each minimal left ideal of the semigroup $\lambda(Q_{2\infty})$ is homeomorphic to the Cantor cube and is algebraically isomorphic to

   $$Q_{2\infty} \times C_{2}^\omega \times c,$$

   where the cardinal $c$ is endowed with the left zero multiplication;

3. the semigroup $\lambda(Q_{2\infty})$ contains a principal ideal isomorphic to

   $$(Q_{2\infty} \wr c) \times C_2 \times (C_2 \wr c)^\omega;$$

4. $\lambda(Q_{2\infty})$ contains an isomorphic copy of each semigroup of cardinality $\leq c$;

5. each maximal subgroup of the minimal ideal $K(\lambda(Q_{2\infty}))$ is topologically isomorphic to $(Q_{2\infty}, \tau) \times C_{2}^\omega$ where $\tau$ is a twin-generated topology on $Q_{2\infty}$;

6. for any twin-generated topology $\tau$ on $Q_{2\infty}$ the right-topological group $(Q_{2\infty}, \tau) \times C_2^\omega$ is topologically isomorphic to a maximal subgroup of $K(\lambda(Q_{2\infty}))$.

**Remark 21.8.** Theorems 21.7(6) and 9.5 imply that among maximal subgroups of the minimal ideal of $\lambda(Q_{2\infty})$ are:
• Raikov complete topological groups,
• incomplete totally bounded topological groups,
• right-topological groups which are not left-topological groups,
• semitopological groups which are not paratopological groups.

21.4. The dihedral 2-groups $D_{2n}$. By the dihedral group $D_{2n}$ of even order $2n$ we understand any group with presentation

$$\langle a, b \mid a^n = b^2 = 1, bab^{-1} = a^{-1} \rangle.$$ 

It can be realized as the group of symmetries of a regular $n$-gon. So, $D_{2n}$ is a subgroup of the orthogonal group $O(2)$. The group $D_{2n}$ contains the cyclic subgroup $C_n = \langle a \rangle$ of index 2. The subgroup of all elements of odd order is normal in $D_{2n}$ and hence coincides with the maximal normal odd subgroup $\text{Odd}$. By Theorem 20.2, the superextension $\lambda(D_{2n})$ is isomorphic to the superextension $\lambda(D_{2n}/\text{Odd})$ of the quotient group $D_{2n}/\text{Odd}$. The latter group is isomorphic to the dihedral group $D_{2^k}$ where $2^k$ is the maximal power of 2 that divides $2n$. Therefore it suffices to consider the superextensions of the dihedral 2-groups $D_{2^k}$.

By the infinite dihedral 2-group we understand the union

$$D_{2^\infty} = \bigcup_{k \in \mathbb{N}} D_{2^k} \subset O(2).$$

It contains the quasicyclic 2-group $C_{2^\infty}$ as a normal subgroup of index 2.

Now we analyze the structure of the superextension $\lambda(D_{2^n})$ for finite $n \geq 1$. Maximal 2-cogroups in $D_{2^n}$ are of the following form:

$$K_0 = D_{2^n} \setminus C_{2^n-1} \text{ and } K_{k,x} = \{1, x\} \cdot (C_{2^k} \setminus C_{2^k-1})$$

where $1 \leq k < n$ and $x \in K_0 = D_{2^n} \setminus C_{2^n-1}$. The characteristic groups of these maximal 2-cogroups are isomorphic to the 2-element cyclic group $C_2$. Also

$$[T_{K_0}] = 1 \text{ and } [T_{K_{k,x}}] = \frac{|2^{D_{2^n} / K_{k,x}^\perp}|}{|H(K)|} = 2^{2^n-k-1}$$

for all $1 \leq k < n$ and $x \in K_0$.

Let $b \in D_{2^n} \setminus C_{2^n-1}$ and $a$ be the generator of the cyclic subgroup $C_{2^n-1} \subset D_{2^n}$. One can check that two 2-cogroups $K_{k,x}$ and $K_{k,y}$ are conjugate if and only if $x^{-1}y \in C_{2^{n-2}}$. Therefore the family

$$\tilde{K} = \{K_0, K_{k,b}, K_{k,ab} : 1 \leq k < n\}$$

is a $\tilde{K}$-selector.

Applying Theorems 18.7, 14.1 and Corollary 18.5(3), we get

**Theorem 21.9.** For every $n \in \mathbb{N}$,

1. the semigroup $\lambda(D_{2^n})$ contains a principal left ideal isomorphic to $C_2 \times \prod_{k=1}^{n-1}(C_2 \wr Z_k)^2$ where $Z_k = 2^{2^n-k-1}$;
2. each minimal left ideal of $\lambda(D_{2^n})$ is isomorphic to $C_2 \times \prod_{k=1}^{n}(C_2 \wr Z_k)^2$ where the cubes $Z_p$ are endowed with the left zero multiplication;
3. each maximal group of the minimal ideal $K(\lambda(D_{2^n+1}))$ is isomorphic to $C_2^{2^{n-1}}$. 

(4) the semigroup $\lambda(D_{2n+1})$ contains an isomorphic copy of each semigroup $S$ of cardinality $|S| < 2^{2^{n-1}-1}$.

The superextension of the infinite dihedral 2-group $D_{2\omega}$ has quite interesting properties. All maximal subgroups of the minimal ideal $K(\lambda(D_{2\omega}))$ are compact topological groups. On the other hand, in the semigroup $\lambda(D_{2\omega})$ there are minimal left ideals which are (or are not) topological semigroups.

**Theorem 21.10.** For the group $D_{2\omega}$

(1) each minimal left ideal of the semigroup $\lambda(D_{2\omega})$ is homeomorphic to the Cantor cube $2^\omega$ and is algebraically isomorphic to the compact topological semigroup $C_2^\omega \times 2^\omega$ where the Cantor cube $2^\omega$ is endowed with the left zero multiplication;

(2) each maximal subgroup of the minimal ideal $K(\lambda(D_{2\omega}))$ is topologically isomorphic to the compact topological group $C_2^\omega$;

(3) $\lambda(D_{2\omega})$ contains a minimal left ideal which is topologically isomorphic to the compact topological semigroup $C_2^\omega \times 2^\omega$;

(4) $\lambda(D_{2\omega})$ contains a minimal left ideal which is not a semitopological semigroup;

(5) the semigroup $\lambda(D_{2\omega})$ contains a principal ideal isomorphic to $C_2 \times (C_2 \times \mathbb{C}^\omega)$;

(6) $\lambda(D_{2\omega})$ contains an isomorphic copy of each semigroup of cardinality $\leq \mathfrak{c}$.

**Proof.** First note that by Theorem 6.2 the torsion group $X = D_{2\omega}$ is twinic and has trivial twinic ideal.

Maximal 2-cogroups in $D_{2\omega}$ are of the following form:

$$K_0 = D_{2\omega} \setminus C_{2\omega} \quad \text{and} \quad K_{k,x} = \{1,x\} \cdot (C_{2k} \setminus C_{2k-1})$$

where $k \in \mathbb{N}$ and $x \in K_0$. The characteristic groups of these maximal 2-cogroups are isomorphic to the 2-element cyclic group $C_2$. Consequently, for any twin set $A \in \hat{T}$ its characteristic group $H(A)$ is topologically isomorphic to $C_2$. Observe that

$$||T_{K_0}|| = 1 \quad \text{and} \quad ||T_{K_{k,x}}|| = 2^\omega$$

for all $k \in \mathbb{N}$ and $x \in K_0$. Since the characteristic group $H(K_{k,x}) = C_2$ is finite, the orbit space $[T_{K_{p,x}}]$ is a compact Hausdorff space, homeomorphic to the Cantor cube $2^\omega$.

One can check that any two 2-cogroups $K_{k,x}$ and $K_{k,y}$ are conjugate. Therefore for any $b \in D_{2\omega} \setminus C_{2\omega}$ the family $\tilde{K} = \{K_0, K_{k,b} : k \in \mathbb{N}\}$ is a $[\tilde{K}]$-selector.

1. By Theorem 18.7(e) and Proposition 12.1, each minimal left ideal of $\lambda(X)$ is homeomorphic to the product $\prod_{K \in \tilde{K}} T_K$, which is homeomorphic to $2^{X/K_0^*} \times \prod_{k \in \mathbb{N}} 2^{X/K_{k,b}}$. The latter space is homeomorphic to the Cantor cube $2^\omega$.

By Theorem 18.7(e), each minimal left ideal of $\lambda(X)$ is algebraically isomorphic to $\prod_{K \in \tilde{K}} H(K) \times [T_K]$ and the latter semigroup is isomorphic to $C_2^\omega \times 2^\omega$ where the Cantor cube $2^\omega$ is endowed with the left zero multiplication.

2. Since each characteristic group $H(A)$, $A \in \hat{T}$, is topologically isomorphic to $C_2$, applying Theorem 18.7(b), we conclude that each maximal subgroup in $K(\lambda(X))$ is topologically isomorphic to the compact topological group $C_2^\omega$.

3. Since each characteristic group $H(K)$, $K \in \tilde{K}$, is finite (being isomorphic to $C_2$), Proposition 18.10 implies that some minimal left ideal of $\lambda(X)$ is a topological semigroup.
which is topologically isomorphic to the compact topological semigroup
\[ \prod_{K \in \mathbb{K}} \mathbb{H}(K) \times \mathbb{T}_K = \mathbb{H}(K_0) \times \mathbb{T}_K \righttimes \prod_{k \in \mathbb{N}} (\mathbb{H}(K_{k,b}) \times \mathbb{T}_{K_{k,b}}) \]
by Theorem \[18.7\](g). The latter topological semigroup is topologically isomorphic to \[C_2^\omega \times 2^\omega\].

4. Since the maximal 2-cogroups \(K_{k,b}, k \in \mathbb{N}\), have infinite index in \(D_{2}\), Proposition \[18.9\] implies that the semigroup \(\lambda(D_{2})\) contains a minimal left ideal which is not a semitopological semigroup.

5. By Corollary \[18.5\](3) and Theorem \[14.1\](3), the semigroup \(\lambda(D_{2})\) contains a principal left ideal that is algebraically isomorphic to the semigroup \(\prod_{K \in \mathbb{K}} (\mathbb{H}(K) \lefttimes \mathbb{T}_K)\), which is isomorphic to \(C_2 \times (C_2 \lefttimes \mathbb{c})^\omega\).

6. By the preceding item, \(\lambda(D_{2})\) contains a subsemigroup isomorphic to the semigroup \(c\) of all self-mappings of the continuum \(c\). By Lemma \[21.2\], the latter semigroup contains an isomorphic copy of each semigroup of cardinality \(\leq c\).

### 21.5. Superextensions of finite groups of order \(< 16\)

Theorem \[19.3\] and Proposition \[19.1\] give us an algorithmic way of calculating the minimal left ideals of the superextensions of finitely-generated abelian groups. For non-abelian groups the situation is a bit more complicated. In this section we shall describe the minimal left ideals of finite groups \(X\) of order \(|X| < 16\).

In fact, Theorem \[20.2\] helps us to reduce the problem to studying superextensions of groups \(X/\text{Odd}\). The group \(X/\text{Odd}\) is trivial if the order of \(X\) is odd. So, it suffices to check non-abelian groups of even order. If \(X\) is a 2-group, then the subgroup \(\text{Odd}\) of \(X\) is trivial and hence \(X/\text{Odd} = X\). Also the subgroup \(\text{Odd}\) is trivial for simple groups.

The table below describes the structure of minimal left ideals of the superextensions of groups \(X = X/\text{Odd}\) of order \(|X| \leq 15\). In this table \(E\) stands for a minimal idempotent of \(\lambda(X)\) which generates the principal left ideal \(\lambda(X) \circ E\) and lies in the maximal subgroup \(H(E) = E \circ \lambda(X) \circ E\). Below, the cubes \(2^n\) are considered as semigroups of left zeros.

| \(X\) | \(|E(\lambda(X) \circ E)|\) | \(E \circ \lambda(X) \circ E\) | \(\lambda(X) \circ E\) |
|-------|-----------------|-----------------|-----------------|
| \(C_2\) | 1               | \(C_2\)        | \(C_2\)        |
| \(C_4\) | 1               | \(C_2 \times C_4\) | \(C_2 \times C_4\) |
| \(C_2^2\) | 1               | \(C_2^3\)      | \(C_2^3\)      |
| \(C_2^3\) | 1               | \(C_2^7\)      | \(C_2^7\)      |
| \(C_2 \oplus C_4\) | 1               | \(C_2^2 \times C_4^2\) | \(C_2^2 \times C_4^2\) |
| \(C_8\) | 2               | \(C_2^5\)      | \(2^2 \times C_2^5\) |
| \(D_8\) | 2               | \(C_3^5\)      | \(2^2 \times C_2^5\) |
| \(Q_8\) | 2               | \(C_3 \times Q_8\) | \(2 \times C_3^2 \times Q_8\) |
| \(A_4\) | \(2^6\)       | \(C_2^3\)      | \(2^6 \times C_2^3\) |

For abelian groups the entries of this table are calculated with the help of Theorem \[19.3\] and Proposition \[19.1\]. Let us illustrate this by the example of the group \(C_2 \oplus C_4\).
By Proposition 19.1 for the group $X = C_2 \oplus C_4$ we get

- $q(X, C_2) = |\hom(X, C_2)| - |\hom(X, C_1)| = 2 \cdot 2 - 1 = 3$;
- $q(X, C_4) = \frac{1}{2}(|\hom(X, C_4)| - |\hom(X, C_2)|) = \frac{1}{2}(2 \cdot 4 - 2 \cdot 2) = 2$;
- $q(X, C_{2k}) = 0$ for $k > 2$.

Then each minimal left ideal of $\lambda(C_2 \oplus C_4)$ is isomorphic to

$$(C_2 \times 2^{2^1-1-1})^{q(X,C_2)} \times (C_4 \times 2^{2^2-2-2})^{q(X,C_4)} = (C_2 \times 2^0)^3 \times (C_4 \times 2^0)^2 = C_2^3 \times C_4^2.$$

Next, we consider the non-abelian groups. In fact, the groups $Q_8$ and $D_8$ have been treated in Theorems 21.6 and 21.9. So, it remains to consider the alternating group $A_4$.

This group has order 12, contains a normal subgroup isomorphic to $C_2 \times C_2$ and contains no subgroup of order 6. This implies that all 2-cogroups of $A_4$ lie in $C_2 \times C_2$, and consequently $A_4$ contains three maximal 2-cogroups. Each maximal 2-cogroup $K \subset A_4$ contains two elements and has characteristic group $H(K)$ isomorphic to $C_2$. Since $|X/K^\perp| = 3$, Proposition 14.2 guarantees that $||T_K|| = 2|X/K^\perp|/|H(K)| = 2^3-1 = 2^2$. Applying Theorem 18.7 we see that each minimal left ideal of the semigroup $\lambda(A_4)$ is isomorphic to $(C_2 \times 2^2)^3 = 2^6 \times C_2^3$.

### 22. Some open problems

**Problem 22.1.** Describe the structure of (minimal left ideals of) superextensions of the simple groups $A_n$ for $n \geq 5$.

**Problem 22.2.** Describe the structure of (minimal left ideals of) superextensions of the finite groups of order 16.

Since the free group $F_2$ with two generators is not twinic, the results obtained in this paper cannot be applied to this group.

**Problem 22.3.** What can be said about the structure of the superextension $\lambda(F_2)$ of the free group $F_2$?

**Problem 22.4.** Investigate the permanence properties of the class of twinic groups. Is this class closed under taking subgroups? products?
