Where to place a comma

Comma

I'll first formulate a few "rules" to follow when using commas in an English text. The rules will then be illustrated by examples.

- Forget the rules of your native tongue.

- Better fewer commas than more.

- Place a comma to separate.

- Place a comma to indicate logical structure.

- Place the main comma, omit the secondary ones.

- Place a comma where the reader should make a pause.

- Do not follow blindly any rules, especially your own.

- Do not modify punctuation in proof-reading unless absolutely necessary.

Forget the rules of your own tongue

In many languages, commas are obligatory before specific words, but not in English:

No comma before 'that':

- We will prove that M is convex.

(Often) no comma before 'which/that':

- Every function which satisfies (2) is called a weak solution of equation (1).

- This holds for every map that appears in Table 2.

In both examples the relative clause ('which satisfies (2)' and 'that appears in Table 2') is *defining* (or "restrictive")—you cannot remove it from the sentence. Defining relative clauses are *not* to be set off by commas.

However, if 'which' starts a non-restrictive clause (an additional comment), the commas should be used:

- The function u, which we have proved to be integrable, is a weak solution of (1).

(In general) no comma before 'if':

- A set is called *closed* if its complement is open.

(Often) there is a comma before 'and':

- A sketch proof is given in Section 6, and we refer the reader to [26] for more details about essential dimension.

- This conjecture was proved by Liebeck, and more recently it has been shown that $c = 7$ is the best possible constant.

We place a comma because the second part starts a new thought.

Place a comma to separate

Place a comma to prevent "false links":

- Thus the proof of Theorem 2, and of the remarks that follow it, is complete. [The comma prevents 'it is complete'.]

- Part (ii) follows immediately from Lemma 2, and part (iii) is an easy consequence of the fact that G has an orbit of dimension n. [The comma prevents 'follows from Lemma 2 and part (iii)'.]

Place a comma to separate symbols:

- For every $x \in X$, Y_x is complete.

Place commas to set off a complementary clause (one that can be omitted without changing the meaning):

- The *base size* of G, denoted by $b(G, H)$ (or just $b(G)$ if the context is clear), is the minimal size of a base for G.

Place a comma before a complementary clause ending a sentence:

- For example, Bochert's result was motivated by the classical problem of bounding the order of a finite primitive permutation group, which attracted a lot of attention in the 19th century.

Use commas to indicate logical structure

In logically complicated sentences, involving alternatives, conjunctions, implications and equivalences, the ranges of particular "operators" may be unclear—then punctuation should help.

For example, if you write 'Then either A or B and C', it is not clear whether you mean

- Then either A or B holds, and moreover C is true,

or

- Then either A holds, or both B and C hold.

Also, do not write 'Then A iff B and C' if you mean 'Then A iff B, and moreover C'. In the latter case (if you do not want to start a new sentence), it is preferable to use a semicolon: 'Then A iff B; moreover, C'.

With very complicated structures, punctuation may not be enough; then a vertical (itemized) arrangement usually helps:

- Since either

  (i) A and $B(x)$ for some x, or
  (ii) D implies $C(x)$ for all x,

  it follows that

  (a) F,
  (b) G.

Place a comma where the reader should pause

- If not, then $K_j = K_j \cap H^g$ for all $g \in G$, which implies that K_j is a positive-dimensional normal subgroup.

- Indeed, the only known exceptions are the cases with H finite.

- A similar argument shows that $b \leq c$, hence equality holds.

- Determining the base size of a given permutation group is a classical problem in permutation group theory, with a long tradition and many applications.

No rules!

In many situations, you can use a comma or not. In each pair of examples below, both sentences have correct punctuation.

1. If A is compact then it is bounded.

2. If A is compact, then it is bounded.

1. In Section 5 we prove Theorem 3.

2. In Section 5, we prove Theorem 3.

1. For every x there exists y such that...

2. For every x, there exists y such that...

1. By (1) the set A is compact.

2. By (1), the set A is compact.

1. Clearly the set A is compact.

2. Clearly, the set A is compact.

However, if expressions like those above are parts of more complicated sentences, too much punctuation may be annoying or even confusing. For example, the sentence

- Since f is compact, by (1), the set A is bounded

is ambiguous: it is not clear which part the phrase 'by (1)' refers to; it is preferable to use one of the versions below:

1. Since f is compact by (1), the set A is bounded.

2. Since f is compact, by (1) the set A is bounded.

This shows that strict adherence to the rule "I always place a comma after «by» phrases" might result in a mistake.

Similarly, even if you (can) place a comma after certain words when they appear at the beginning of a sentence, the comma is no more necessary in the middle:

1. Moreover, F is continuous.

2. Then F is continuous, and moreover we can approximate it by functions satisfying (5). [or without a comma before 'and']

1. Consequently, F is continuous.

2. Then F is continuous, and consequently we can approximate it by functions satisfying (5). [or without a comma before 'and']

Not by comma alone...

Sentences containing mathematical expressions separated only by commas are difficult to read, and their logical structure may be unclear. Replacing commas by words makes things clearer and spares the reader's effort.

Here is an example:

- Then $f(x) > 0$, $x \in X$.

At least formally, one can understand it in several ways:

- Then $f(x) > 0$ and $x \in X$.

- Then $f(x) > 0$ for all $x \in X$.

- Then $f(x) > 0$ for some $x \in X$.

Moreover, remember a quite popular convention: a displayed formula

$$f(x) > 0, \qquad x \in X,$$

will be understood as '$f(x) > 0, \forall x \in X$' by most readers. If you mean $\exists$, write

$$\exists x \in X, \quad f(x) > 0.$$

Commas in lists

You can write either

- Cox, Brown and Fox,

or

- Cox, Brown, and Fox

(various manuals recommend one of these versions, but there is no general agreement, neither in British nor in American publications). Adding a comma is always recommended if it helps to avoid ambiguity.

Semicolon

Use a semicolon between two sentences if they are of "comparable power", but you do not want to separate them by a full stop:

- Using Theorem 6 we can compute the precise value of $A(v)$ in almost all cases; this is a significant strengthening of the general estimate $A(v) \le 2$ stated in [6].

- A subset of Ω is a *base* for G if its pointwise stabilizer is trivial; the *base size* of G is the minimal cardinality of a base.

- Then $f_1 = g_1$ in D_1; and since D_2 is connected, we also have $f_1 = g_1$ in D_2.

Use a semicolon between items of a list when the items are long and complex or involve commas:

- Here A, B and C are complex numbers depending on x, y and z; D and E depend on c and d; and F is given by Lemma 5.

Colon

Do not use a colon before a list within the same sentence:

- The group G can be of type A, B, C or D.

- Consider all elements $x \in X$ such that (i) ..., (ii) ..., and (iii) ...

However, if the list is "vertical", you can use a colon or not; its use is advisable if the items have internal punctuation:

- Consider all elements $x \in X$ such that:

  (i) $Ax = 1$, $Bx = 0$, $Cx = 2$—we then say that x is $(1, 0, 2)$-regular;
  (ii) ...;
  (iii) ...

Items in a vertical list may end with a comma or a semicolon; if the items are complete sentences, you may start them with a capital letter and end with a full stop.

Use a colon before a list when the sentence preceding the list is complete (e.g. contains 'the following' or 'as follows'):

- The group G can be of four types: A, B, C or D.

- Consider all elements $x \in X$ such that one of the following holds:

  (i) ...;
  (ii) ...

You can place a colon between two sentences if the second explains, illustrates, paraphrases or gives more detail about the first:

- Here is a more explicit statement of what the theorem asserts: if γ can be continued analytically along C_1 to f_1, and if it can also be continued analytically along C_2 to f_2, then $f_1 = f_2$ in $C_1 \cap C_2$.

- A few S-invariant subspaces are immediately apparent: if Y_k is the set of all x whose first k coordinates are 0, then Y_k is S-invariant.

If the explanation after the colon involves more than one sentence, start it with a capital letter:

- Actually, H^p is a Banach space: To prove the completeness, let (f_n) be a Cauchy sequence in H^p. Then...

Do *not* place a comma before every displayed formula.

Dash

The dash is used (and set in print) in English in a different way than in many other languages.

Sudden break:

- Recall the interior tensor product $A \otimes B$—this is a right module over C.

- The first inequality is well known—see [5, Proposition 3.1].

In the last sentence, using a comma instead of a dash is not a good idea (although very popular); a semicolon is not good either because the second sentence is evidently "subordinate". Other possible punctuations in this case:

- The first inequality is well known: see [5, Proposition 3.1].

- The first inequality is well known (see [5, Proposition 3.1]).

- The first inequality is well known [5, Proposition 3.1].

In the last example, you do not need to add ( ): the square brackets are good enough. For citations, the last variant—the simplest one—seems to be the best.

The dash is not used to avoid repetitions:

Do not use a dash to replace a word you do not want to repeat:

- We denote the former set by A, and the latter by B. [not 'the latter—by B']

Hyphen

In the spelling of many words, you can use a hyphen or not, but be consistent within each document:

Non(-):

You can write either

- nontrivial, nonzero, nonnegative,

or

- non-trivial, non-zero, non-negative.

However, always write

- non-Euclidean, non-locally convex [or even better 'non-locally-convex' because what you are negating here is not just 'locally'].

Hyphen mandatory:

- one-parameter group

- one-to-one map

- two-stage computation

- n-fold integration

The hyphen is useful (and necessary) when e.g. you want to make several words joined by prepositions and/or conjunctions into one "qualifier":

- a local-to-global method, an easy-to-trace element

Hyphen optional:

- right hand side, right-hand side

- second order equation, second-order equation

- selfadjoint, self-adjoint

- seminorm, semi-norm

- a blow-up, a blow up, a blowup [but always 'to blow up' (a verb)]

- the nth element, the n-th element

- above-mentioned, above mentioned

A general remark: nowadays, hyphens tend to be less and less used: the expressions that used to be hyphenated are now often written as one word without a hyphen or as two separate words.
Personally, I'd always write 'a finite-dimensional space', 'a model-theoretic construction', but these expressions are now very often written as separate words.

N-rule:

In several cases, a double hyphen is used ("N-rule");

- pages 12–34, items (i)–(iv), Sections 2.3–2.7

- Radon–Nikodym theorem [for two names, but 'Piatetski-Shapiro' because this is one name]
