Fourier-like methods for equations with separable variables
FOURIER-LIKE METHODS FOR EQUATIONS
WITH SEPARABLE VARIABLES

D. Przeworska-Rolewicz (Warszawa)

It is well known that a power of a right invertible operators is again right invertible, as well as a polynomial in a right invertible operator under appropriate assumptions. However, a linear combination of right invertible operators (in particular, their sum and/or difference) in general is not right invertible. It will be shown how to solve equations with linear combinations of right invertible operators in commutative algebras using properties of logarithmic and antilogarithmic mappings. The used method is, in a sense, a kind of the variables separation method. We shall obtain also an analogue of the classical Fourier method for partial differential equations. Note that results concerning the Fourier method are proved under weaker assumptions than those obtained in PR[1] (cf. also PR[2], PR[3], PR[6]).

1. Preliminaries. Basic notions of Algebraic Analysis

We recall here the following notions and theorems (without proofs; cf. PR[2], PR[3]). Denote by \( \mathbb{N}, \mathbb{N}_0, \mathbb{R}, \mathbb{C}, \mathbb{Z}, \mathbb{Q} \) the sets of positive integers, nonnegative integers, reals, complexes, integers and rational numbers, respectively, and by \( \mathbb{F} \) any field of scalars. If \( \mathbb{F} \) is a field of numbers then by \( \mathbb{F}[t] \) is denoted the set of all polynomials in \( t \) with coefficients in \( \mathbb{F} \).

Let \( X \) be a linear space (in general, without any topology) over a field \( \mathbb{F} \) of scalars of the characteristic zero.

- \( L(X) \) is the set of all linear operators with domains and ranges in \( X \);
- \( \text{dom} \ A \) is the domain of an \( A \in L(X) \);
- \( \ker A = \{ x \in \text{dom} \ A : Ax = 0 \} \) is the kernel of an \( A \in L(X) \);
- \( L_0(X) = \{ A \in L(X) : \text{dom} \ A = X \} \);
- \( I(X) \) is the set of all invertible elements in \( X \).

Key words: algebraic analysis, commutative algebra with unit, Leibniz condition, logarithmic mapping, antilogarithmic mapping, right invertible operator, sine mapping, cosine mapping, initial value problem, boundary value problem, Fourier method

2000 AMS Subject Classification: 47 A 25, 47 C 05, 47 N 20, 35 A 25
An operator $D \in L(X)$ is said to be right invertible if there is an operator $R \in L_0(X)$ such that $RX \subset \operatorname{dom} D$ and $DR = I$, where $I$ denotes the identity operator. The operator $R$ is called a right inverse of $D$. By $R(X)$ we denote the set of all right invertible operators in $L(X)$. Let $D \in R(X)$. Let $\mathcal{R}_D \subset L_0(X)$ be the set of all right inverses for $D$, i.e. $DR = I$ whenever $R \in \mathcal{R}_D$. We have $\operatorname{dom} D = RX \oplus \ker D$, independently of the choice of an $R \in \mathcal{R}_D$. Elements of $\ker D$ are said to be constants, since by definition, $Dz = 0$ if and only if $z \in \ker D$. The kernel of $D$ is said to be the space of constants. We should point out that, in general, constants are different than scalars, since they are elements of the space $X$. If two right inverses commute each with another, then they are equal.

Clearly, if $\ker D \neq \{0\}$ then the operator $D$ is right invertible, but not invertible. Here the invertibility of an operator $A \in L(X)$ means that the equation $Ax = y$ has a unique solution for every $y \in X$. An element $y \in \operatorname{dom} D$ is said to be a primitive for an $x \in X$ if $y = Rx$ for an $R \in \mathcal{R}_D$. Indeed, by definition, $x = DRx = Dy$. Again, by definition, all $x \in X$ have primitives. Let

$$\mathcal{F}_D = \{ F \in L_0(X) : F^2 = F; FX = \ker D \text{ and } \exists R \in \mathcal{R}_D FR = 0 \}.$$  

Any $F \in \mathcal{F}_D$ is said to be an initial operator for $D$ corresponding to $R$. One can prove that any projection $F'$ onto $\ker D$ is an initial operator for $D$ corresponding to a right inverse $R' = R - F'R$ independently of the choice of an $R \in \mathcal{R}_D$.

If two initial operators commute each with another, then they are equal. Thus this theory is essentially noncommutative. An operator $F$ is initial for $D$ if and only if there is an $R \in \mathcal{R}_D$ such that

$$\tag{1.1} F = I - RD \quad \text{on } \operatorname{dom} D.$$  

It is enough to know one right inverse in order to determine all right inverses and all initial operators. Note that a superposition of a finite number of right invertible operators is again a right invertible operator.

The equation $Dx = y \ (y \in X)$ has the general solution $x = Ry + z$, where $R \in \mathcal{R}_D$ is arbitrarily fixed and $z \in \ker D$ is arbitrary. However, if we put an initial condition: $Fx = x_0$, where $F \in \mathcal{F}_D$ and $x_0 \in \ker D$, then this equation has a unique solution $x = Rx + x_0$.

If $T \in L(X)$ belongs to the set $\Lambda(X)$ of all left invertible operators, then $\ker T = \{0\}$. If $D$ is invertible, i.e. $D \in \mathcal{I}(X) = R(X) \cap \Lambda(X)$, then $\mathcal{F}_D = \{0\}$ and $\mathcal{R}_D = \{D^{-1}\}$.

If $P(t) \in \mathbb{F}[t]$ then all solutions of the equation $P(D)x = y$, $y \in X$, can be obtained by a decomposition of the rational function $1/P(t)$ into vulgar fractions.

Write

$$\nu_{g,A} = \{ \lambda \in \mathbb{F} \setminus \{0\} : I - \lambda A \text{ is invertible} \} \quad \text{for } A \in L(X)$$
Clearly, $\lambda \in \mathbb{V}A$ and only if $1/\lambda$ is a regular value of $A$. Let $V(X)$ be the set of all Volterra operators, i.e.

$$V(X) = \{ A \in L_0(X) : A - \lambda I \text{ is invertible for all } \lambda \in \mathbb{F} \setminus \{0\} \}.$$ 

Then $A \in V(X)$ if and only if $\mathbb{V}A = \mathbb{F} \setminus \{0\}$.

If $X$ is an algebra over $\mathbb{F}$ with a $D \in L(X)$ such that $x, y \in \text{dom } D$ implies $xy, yx \in \text{dom } D$, then we say that $X$ is a $D$-algebra and we write $D \in \mathbb{A}(X)$. The set of all commutative algebras belonging to $\mathbb{A}(X)$ will be denoted by $\mathbb{A}(X)$. Let $D \in \mathbb{A}(X)$ and

$$f_D(x, y) = D(xy) - c_D[xDy + (Dx)y] \quad \text{for } x, y \in \text{dom } D,$$

where $c_D$ is a scalar dependent on $D$ only. Clearly, $f_D$ is a bilinear (i.e. linear in each variable) form which is symmetric when $X$ is commutative, i.e. when $D \in \mathbb{A}(X)$. This form is called a non-Leibniz component (cf. PR[2]). If $D \in \mathbb{A}(X)$ then the product rule in $X$ can be written as follows:

$$D(xy) = c_D[xDy + (Dx)y] + f_D(x, y) \quad \text{for } x, y \in \text{dom } D.$$

If $D \in \mathbb{A}(X)$ and if $D$ satisfies the Leibniz condition:

$$D(xy) = xDy + (Dx)y \quad \text{for } x, y \in \text{dom } D,$$

then $X$ is said to be a Leibniz algebra. It means that in Leibniz algebras $c_D = 1$ and $f_D = 0$. The Leibniz condition implies that $xy \in \text{dom } D$ whenever $x, y \in \text{dom } D$, i.e. Leibniz algebras are $D$-algebras. If $X$ is a Leibniz algebra with unit $e$ then $e \in \ker D$, i.e. $D$ is not left invertible. The set of commutative Leibniz $D$-algebras $X$ with a $D \in R(X)$ and with unit $e \in \text{dom } D$ is denoted by $L(D)$. Clearly, if $X \in L(D)$ then $e \in \ker D$.

Non-Leibniz components for powers of $D \in \mathbb{A}(X)$ are determined by recurrence formulae (cf. PR[2], PR[3]).

Suppose that $D \in \mathbb{A}(X)$ and $\lambda \neq 0$ is an arbitrarily fixed scalar. Then $\lambda D \in \mathbb{A}(X)$ and $c_{\lambda D} = c_D$, $f_{\lambda D} = \lambda f_D$.

If $D_1, D_2 \in \mathbb{A}(X)$, the superposition $D = D_1 D_2$ exists and $D_1 D_2 \in \mathbb{A}(X)$, then

$$c_{D_1 D_2} = c_{D_1} c_{D_2} \quad \text{and for } x, y \in \text{dom } D = \text{dom } D_1 \cap D_2$$

$$f_{D_1 D_2}(x, y) = f_{D_1}(x, y) + D_1 f_{D_2}(x, y) + +c_{D_1} c_{D_2}[(D_1 x)D_2 y + (D_2 x)D_1 y].$$

For higher powers of $D$ in Leibniz algebras, by an easy induction from Formulae (1.4) and the Leibniz condition, we obtain the Leibniz formula:

$$D^n(xy) = \sum_{k=0}^{n} \binom{n}{k} (D^k x) D^{n-k} y \quad \text{for } x, y \in \text{dom } D^n \quad (n \in \mathbb{N}).$$
Let $X \in A(X)$. Denote by the set $M(X)$ of all multiplicative mappings (not necessarily linear) with domains and ranges in $X$:

$$M(X) = \{ A : A(xy) = (Ax)(Ay) \text{ whenever } x, y \in \text{dom } A \subset X \}.$$ 

Suppose that $X \in A(X)$ and $D \in R(X)$. An initial operator $F$ for $D$ is said to be almost averaging if $F(zx) = zFx$ whenever $z \in \ker D, x \in X$. Clearly, every multiplicative operator $F \in \mathcal{F}_D$ is almost averaging for $F(zx) = (Fz)(Fx) = zFx$ if $z \in \ker D, x \in X$, but not conversely (cf. PR[2]).

Suppose that $D \in A(X)$. Let a multifunction $\Omega : \text{dom } D \rightarrow 2^{\text{dom } D}$ be defined as follows:

\begin{equation}
\Omega u = \{ x \in \text{dom } D : Du = uDx \} \text{ for } u \in \text{dom } D.
\end{equation}

The equation

\begin{equation}
Du = uDx \text{ for } (u, x) \in \text{graph } \Omega
\end{equation}

is said to be the basic equation. Clearly,

$$\Omega^{-1} x = \{ u \in \text{dom } D : Du = uDx \} \text{ for } x \in \text{dom } D.$$ 

The multifunction $\Omega$ is well-defined and $\text{dom } \Omega \supset \ker D \setminus \{0\}$.

Suppose that $(u, x) \in \text{graph } \Omega$, $L$ is a selector of $\Omega$ and $E$ is a selector of $\Omega^{-1}$. By definitions, $Lu \in \text{dom } \Omega^{-1}$, $Ex \in \text{dom } \Omega$ and the following equations are satisfied:

$$Du = uDLu, \quad DEx = (Ex) Dx.$$ 

Any invertible selector $L$ of $\Omega$ is said to be a logarithmic mapping and its inverse $E = L^{-1}$ is said to be a antilogarithmic mapping. By $G[\Omega]$ we denote the set of all pairs $(L, E)$, where $L$ is an invertible selector of $\Omega$ and $E = L^{-1}$. For any $(u, x) \in \text{dom } \Omega$ and $(L, E) \in G[\Omega]$ elements $Lu, Ex$ are said to be logarithm of $u$ and antilogarithm of $x$, respectively. The multifunction $\Omega$ is examined in PR[3] and following papers (also for noncommutative algebras).

Clearly, by definition, for all $(L, E) \in G[\Omega], (u, x) \in \text{graph } \Omega$ we have

\begin{equation}
ELu = u, \quad LEx = x; \quad DEx = (Ex) Dx, \quad Du = uDLu.
\end{equation}

A logarithm of zero is not defined. If $(L, E) \in G[\Omega]$ then $L(\ker D \setminus \{0\}) \subset \ker D$, $E(\ker D) \subset \ker D$. In particular, $E(0) \in \ker D$.

If $D \in R(X)$ then logarithms and antilogarithms are uniquely determined up to a constant. Moreover, if $F \in \mathcal{F}_D$ then $FE = EF, FL = LF$ (cf. PR[10]).
Let $D \in A(X)$ and let $(L, E) \in G[\Omega]$. A logarithmic mapping $L$ is said to be of the exponential type if $L(uv) = Lu + Lv$ for $u, v \in \text{dom } \Omega$. If $L$ is of the exponential type then $E(x + y) = (Ex)(Ey)$ for $x, y \in \text{dom } \Omega^{-1}$. We have proved that a logarithmic mapping $L$ is of the exponential type if and only if $X$ is a Leibniz commutative algebra (cf. PR[3]). Moreover, $Le = 0$, i.e. $E(0) = e$. In Leibniz commutative algebras with $D \in R(X)$ a necessary and sufficient conditions for $u \in \text{dom } \Omega$ is that $u \in I(X)$ (cf. PR[3]).

By $\text{Lg}(D)$ we denote the class of these commutative algebras with $D \in R(X)$ and with unit $e \in \text{dom } \Omega$ for which there exist invertible selectors of $\Omega$, i.e. there exist $(L, E) \in G[\Omega]$. By $L(D)$ we denote the class of these commutative Leibniz algebras with unit $e \in \text{dom } \Omega$ for which there exist invertible selectors of $\Omega$. By these definitions, $X \in \text{Lg}(D)$ is a Leibniz algebra if and only if $X \in L(D)$ and $D \in R(X)$. This class we shall denote by $L(D)$. It means that $L(D)$ is the class of these commutative Leibniz algebras with $D \in R(X)$ and with unit $e \in \text{dom } \Omega$ for which there exist invertible selectors of $\Omega$, i.e. there exist $(L, E) \in G[\Omega]$.

In the same manner we define logarithmic and antilogarithmic mappings of higher order. Namely, let $n \in \mathbb{N}$ be arbitrarily fixed. Suppose that $D \in A(X)$. Let a multifunction $\Omega_n : \text{dom } D^n \rightarrow 2^{\text{dom } D^n}$ be defined as follows:

\[(1.7) \quad \Omega_n u = \{x \in \text{dom } D^n : D^nu = uD^nx\} \quad \text{for } u \in \text{dom } D^n.\]

Any invertible selector $L_n$ of $\Omega_n$ is said to be a logarithmic mapping of the order $n$ and its inverse $E_n = L_n^{-1}$ is said to be a antilogarithmic mapping of the order $n$. By $G[\Omega_n]$ we denote the set of all pairs $(L_n, E_n)$, where $L_n$ is an invertible selector of $\Omega_n$ and $E_n = L_n^{-1}$. For any $(u, x) \in \text{dom } \Omega_n$ and $(L_n, E_n) \in G[\Omega_n]$ elements $L_nu, E_nx$ are said to be logarithm of the order $n$ of $u$ and antilogarithm of the order $n$ of $x$, respectively. The multifunctions $\Omega_n$ and relations between them are examined in PR[3]. Clearly, if $X \in \text{Lg}(D)$ then $X \in \text{Lg}(D^n)$ for all $n \in \mathbb{N}$.

If $\ker D = \{0\}$ then either $X$ is not a Leibniz algebra or $X$ has no unit (cf. PR[3]). Thus, by our definition, if $X \in L(D)$ then $\ker D \neq \{0\}$, i.e. the operator $D$ is right invertible but not invertible.

2. Linear combinations of right invertible operators.

We begin with

**Proposition 2.1.** Suppose that $n, r_1, ..., r_n \in \mathbb{N}$,

\[(2.1) \quad X \in \bigcap_{j=1}^{n} L(D_j),\]

\[(2.2) \quad D = \sum_{j=1}^{n} \alpha_j D_j^{r_j}, \quad \alpha_j \in X \quad (j = 1, ..., n), \quad \text{dom } D = \bigcap_{j=1}^{n} \text{dom } D_j^{r_j} \neq \emptyset,\]
(L_{r_j}, E_{r_j}) \in G[\Omega_{r_j}], \text{ where } \Omega_{r_j} \text{ is induced by } D_{r_j}^m \ (j = 1, ..., n),

(2.3) \quad x = \prod_{k=1}^{n} u_k, \quad \text{ where } u_k \in \ker D_k \cap I(X) \quad (k = 1, ..., n),

Then

(2.4) \quad Dx = ax, \quad \text{ where } a = \sum_{j=1}^{n} \alpha_j a_j,

(2.5) \quad a_j = D_{r_j}^m L_{r_j}^{(j)} \tilde{u}_j \quad \text{ and } \quad \tilde{u}_j = \prod_{k=1, k \neq j}^{n} u_k \quad (j = 1, ..., n),

i.e. \( \tilde{u}_j \), \( u_j \tilde{u}_j = x \in I(X) \ (j = 1, ..., n) \).

**Proof.** Since by our assumptions, the operators \( D_1, ..., D_n \) satisfy the Leibniz condition and \( D_1 u_1 = ... = D_n u_n = 0 \), from the Leibniz Formula (1.5) we get

\[
D_m^m x = D_m^m (\prod_{k=1}^{n} u_k) = \sum_{l=0}^{m} \binom{m}{l} (D_l^l u_j) (D_{m-l}^m \tilde{u}_j) = u_j D_m^m \tilde{u}_j
\]

for \( j = 1, ..., n \). Thus

\[
Dx = \left( \sum_{j=1}^{n} \alpha_j D_{r_j}^j \right) \prod_{k=1}^{n} u_k =
\]

\[
= \sum_{j=1}^{n} \alpha_j u_j D_{r_j}^j \prod_{k=1, k \neq j}^{n} u_k =
\]

\[
= \left( \prod_{k=1}^{n} u_k \right) \sum_{j=1}^{n} \alpha_j \left( \prod_{k=1, k \neq j}^{n} u_k^{-1} \right) D_{r_j}^j \left( \prod_{k=1, k \neq j}^{n} u_k \right) =
\]

\[
x \sum_{j=1}^{n} \alpha_j \tilde{u}_j^{-1} D_{r_j}^j \tilde{u}_j = x \sum_{j=1}^{n} \alpha_j D_{r_j}^j L_{r_j}^{(j)} \tilde{u}_j = x \sum_{j=1}^{n} \alpha_j a_j = xa.
\]

\[\blacksquare\]

**Proposition 2.2.** Suppose that all assumptions of Proposition 2.1 are satisfied. Then there are \( R_j \in R_{D_j} \) such that \( R_j^r a_j \in \text{dom } (\Omega_{r_j})^{-1} \ (j = 1, ... n) \) and

(2.6) \quad \tilde{u}_j = E_{r_j}^{(j)} (R_j^r a_j) \quad (j = 1, ..., n).
Proof. By our assumptions, \( a_j = D_j^{r_j} L_j^{(j)} \tilde{u}_j \) for \( j = 1, \ldots, n \). Hence there are \( R_j \in \mathcal{R}_D \) such that \( L_j^{(j)} \tilde{u}_j = R_j^{r_j} a_j \) (cf. PR[3]), i.e. \( \tilde{u}_j = E_j^{(j)} L_j^{(j)} \tilde{u}_j = E_j^{(j)} (R_j^{r_j} a_j) \). ■

**Proposition 2.3.** Suppose that all assumptions of Proposition 2.1 are satisfied and \( r_1 = \ldots = r_n = 1 \). Then the operator \( D \) defined by (2.2) satisfies the Leibniz condition.

Proof. Let \( x, y \in \text{dom} \, D \). Clearly, \( x, y \in \text{dom} \, D \) whenever \( x, y \in \bigcap_{j=1}^n \text{dom} \, D_j \). Since \( D_1, \ldots, D_n \) satisfy the Leibniz condition, we get

\[
D(xy) = \sum_{j=1}^n \alpha_j D_j(xy) = \sum_{j=1}^n \alpha_j (xD_jy + yD_jx) = \\
x \sum_{j=1}^n \alpha_j D_jy + y \sum_{j=1}^n \alpha_j D_jx = xDy + yDx.
\]

■

**Proposition 2.4.** Suppose that all assumptions of Proposition 2.1 are satisfied. Let

\[
(2.7) \quad U_n = \left\{ \prod_{k=1}^n u_k : u_k \in \ker D_k \cap I(X) \quad (k = 1, \ldots, n) \right\} \quad (n \in \mathbb{N}).
\]

Then selectors \( L \) of the multifunction \( \Omega \) induced by \( D \) satisfy the equality \( DLx = a \) for \( x \in U_n \).

Proof. By Equation (2.4), we have \( Dx = ax \), where \( x \in I(X) \). Thus, by definition, \( DLx = x^{-1}Dx = a \) for any selector \( L \) of \( \Omega \). ■

This, and Proposition 2.3 together imply

**Corollary 2.1.** Suppose that all assumptions of Proposition 2.1 are satisfied. If \( r_1 = \ldots = r_n = 1 \) and \( U_n \in \text{Lg}(D) \) then \( U_n \in \text{L}(D) \).

**Proposition 2.5.** Suppose that all assumptions of Proposition 2.1 are satisfied and \( a = 0 \). Then there are \( R_j \in \mathcal{R}_D \) such that \( R_j^{r_j} a_j \in \text{dom} \left( \Omega_{r_j}^{(j)} \right)^{-1} \) \( (j = 1, \ldots, n) \) and

\[
(2.8) \quad x = \frac{1}{n} \sum_{j=1}^n u_j \tilde{u}_j = \frac{1}{n} \sum_{j=1}^n u_j E_r^{(j)} (R_j^{r_j} a_j) \in \ker D,
\]

where \( u_j \in \ker D_j \cap I(X) \) \( (j = 1, \ldots, n) \).

Proof. By our assumptions and Proposition 2.1, \( Dx = ax = 0 \) and \( x = u_j \tilde{u}_j \) \( (j = 1, \ldots, n) \). Hence \( x = \frac{1}{n} \sum_{j=1}^n u_j \tilde{u}_j \). This, and Proposition 2.2 together imply (2.8). ■
Proposition 2.6. Suppose that all assumptions of Proposition 2.1 are satisfied and \( a \in I(X) \). Then the equation

\begin{equation}
Dx = y, \quad y \in X
\end{equation}

has a solution

\begin{equation}
x = y\left(\sum_{j=1}^{n} \alpha_j D^{r_j}_j L^{(j)} \tilde{u}_j\right)^{-1}
\end{equation}

Proof. By our assumptions, \( ax = Dx = y \). Since \( a \in I(X) \), we get \( x = a^{-1}y \). Propositions 2.1 and 2.2 together imply that

\[ x = a^{-1}y = y\left(\sum_{j=1}^{n} \alpha_j a_j\right)^{-1} = y\left(\sum_{j=1}^{n} \alpha_j D^{r_j}_j L^{(j)} \tilde{u}_j\right)^{-1}. \]

\[ \square \]

Corollary 2.2. Suppose that all assumptions of Proposition 2.1 are satisfied, \( r_1 = \ldots = r_n = 1 \) and \( a \in I(X) \). Then the equation (2.9) has a solution

\begin{equation}
x = y\left(\sum_{j=1}^{n} \alpha_j D^j \sum_{k=1, k \neq j}^{n} L^{(j)}_k u_k\right)^{-1}.
\end{equation}

Proof. Proposition 2.6 and the Leibniz condition together imply that

\[ x = y\left(\sum_{j=1}^{n} \alpha_j D^j L^{(j)} \prod_{k=1, k \neq j}^{n} u_k\right)^{-1} = y\left(\sum_{j=1}^{n} \alpha_j D^j \sum_{k=1, k \neq j}^{n} L^{(j)}_k u_k\right)^{-1}. \]

\[ \square \]

Some more generalized approaches to problems with linear combinations of right invertible operators of order one have on vectors fields and magnifolds have been given by Virsik V[1] and Multarzyński M[1], M[2].

3. Trigonometric elements and mappings.

We shall show now an approach to the trigonometric identity in Leibniz \( D \)-algebras with unit \( e \) (but not necessarily with logarithms). Clearly, without additional assumptions we cannot expect too much.

Proposition 3.1. Suppose that \( X \in L(D) \), \( x \in \text{dom } D^2 \) and \( x, Dx \) are not zero divisors. If \( x^2 + (Dx)^2 = e \) then

\begin{equation}
\alpha x + \beta Dx \in \ker (D^2 + I) \quad \text{whenever } \alpha, \beta \in \mathbb{F}.
\end{equation}
Proof. Let \( y = -Dx \). Then \( Dy = -D^2x \) and

\[
0 = De = D[x^2 + (Dx)^2] = 2xDx + 2(Dx)D^2x = 2(Dx)(x + D^2x) = 2y(x - Dy).
\]

Since \( y = -Dx \) is not a zero divisor, we have \( x - 2y = 0 \). Hence \( Dy = x \) and \( y = -Dx = -D^2y \), which implies \( y \in \ker (D^2 + I) \). On the other hand, \( x = Dy = -D^2x \), which implies \( x \in \ker (D^2 + I) \).

**Proposition 3.2.** Suppose that all assumptions of Proposition 3.1 are satisfied. If Condition (3.1) hold for \( x \) and \( Dx \) and \( u = x^2 + (Dx)^2 \) then \( u \in \ker D \).

Proof. Let \( u = x^2 + (Dx)^2 \). Then \( Du = 2xDx + 2(Dx)D^2x = 2(Dx)(x + Dx) = 2(Dx)(D^2 + I)x = 0 \), which implies \( u \in \ker D \).

**Corollary 3.1.** Suppose that all assumptions of Proposition 3.1 are satisfied, Condition (3.1) holds for \( x \) and \( Dx \), \( F \in \mathcal{F}_D \cap \mathcal{M}(X) \), \( Fx = e \), \( FDx = 0 \) and \( u = x^2 + (Dx)^2 \). Then \( u = e \), i.e. \( x^2 + (Dx) = e \).

Proof. Since \( F \) is a multiplicative initial operator and \( Fx = e \), \( FDx = 0 \), we find \( u = F[x^2 + (Dx)^2] = (Fx)^2 + (FDx)^2 = e^2 + 0 = e \).

**Proposition 3.3.** Suppose that all assumptions of Proposition 3.1 and Condition (3.1) are satisfied, \( F \in \mathcal{F}_D \cap \mathcal{M}(X) \) and \( Fx = e \). Then \( FDx = 0 \).

Proof. By our assumptions, \( e = Fe = F[x^2 + (Dx)^2] = (Fx)^2 + (FDx)^2 = e + (FDx)^2 \), which implies \( (FDx)^2 = 0 \). Hence \( FDx = 0 \).

**Proposition 3.4.** Suppose that all assumptions of Proposition 3.1 are satisfied. If \( x_+ \in \ker (D \pm iI) \) and \( x = \frac{1}{2}(x_+ + x_-) \), \( y = \frac{1}{2}(x_+ - x_-) \), then

(i) \( x, y \in \ker (D^2 + I), Dx = -y, Dy = x \) and \( \frac{1}{2}(x \pm y) \in \ker (D^2 \mp iI) \);

(ii) \( x^2 + y^2 = x_+x_- \in \ker D \).

Proof. Points (i) is proved by checking. In order to prove (ii), observe that, by the Leibniz condition and our assumptions,

\[
D(x_+x_-) = x_+Dx_- + x_-Dx_+ = ix_+x_- - ix_+x_- = 0.
\]

Observe that \( x_\pm \) are eigenvectors of the operator \( D \) corresponding to the eigenvalues \( \mp i \), respectively.

Here and in the sequel we assume that \( \mathbb{F} \) is an algebraically closed field of scalars. For instance, \( \mathbb{F} = \mathbb{C} \). The following results are slightly stronger (with some proofs slightly simpler than in PR[2]):

**Definition 3.1.** Let \( X \) be a linear space over \( \mathbb{F} \). If \( \lambda \in \mathbb{F} \) is an eigenvalue of an operator \( D \in \mathcal{R}(X) \) then every eigenvector \( x_\lambda \) corresponding to \( \lambda \) is said to be an exponential element (shortly: an exponential).
This means that $x_\lambda$ is an exponential if and only if $x_\lambda \neq 0$ and $x_\lambda \in \ker(D - \lambda I)$.

**Proposition 3.5.** Let $X$ be a linear space (over $\mathbb{F}$). Suppose that $D \in R(X)$. If $0 \neq x_\lambda \in \ker(I - \lambda R)$ for an $R \in \mathcal{R}_D$ and a $\lambda \in \mathbb{F}$ then $x_\lambda \in \ker(D - \lambda I)$, i.e. $x_\lambda$ is an exponential.

**Proof.** By our assumption, $(D - \lambda I)x_\lambda = (D - \lambda DR)x_\lambda = D(I - \lambda R)x_\lambda = 0$. ■

By an easy induction we prove

**Proposition 3.6.** Suppose that $X$ is a linear space (over $\mathbb{F}$), $D \in R(X)$, $\{\lambda_n\} \subset \mathbb{F}$ is a sequence of eigenvalues such that $\lambda_i \neq \lambda_j$ for $i \neq j$. Then for an arbitrary $n \in \mathbb{N}$ the exponentials $x_{\lambda_1},...,x_{\lambda_n}$ are linearly independent.

**Proposition 3.7** Suppose that $X$ is a linear space (over $\mathbb{F}$), $D \in R(X)$, $F$ is an initial operator for $D$ corresponding to an $R \in \mathcal{R}_D$ and $x_\lambda$ is an exponential. Then $x_\lambda$ is an eigenvector for $R$ corresponding to the eigenvalue $1/\lambda$ if and only if $Fx_\lambda = 0$, i.e. if $R$ is not a Volterra operator.

**Proof.** Sufficiency. Since $Dx_\lambda = \lambda x_\lambda$ and $Fx_\lambda = 0$, we get $x_\lambda = x_\lambda - Fx_\lambda = (I - F)x_\lambda = RDx_\lambda = \lambda Rx_\lambda$. Hence $x_\lambda \in \ker(I - \lambda R)$. Since $x_\lambda \neq 0$, we conclude that $x_\lambda$ is an eigenvector for $R$ corresponding to $1/\lambda$.

Necessity. Suppose that $1/\lambda$ is an eigenvalue of $R$ and the corresponding eigenvector $x_\lambda$ is an exponential. Then $Fx_\lambda = (I - RD)x_\lambda = (I - \lambda R)x_\lambda = -\lambda(R - \frac{1}{\lambda}I)x_\lambda = 0$. ■

**Theorem 3.1.** Suppose that $X$ is a linear space (over $\mathbb{F}$), $D \in R(X)$, $\ker D \neq \{0\}$, $R \in \mathcal{R}_D$ and $\lambda \in v_p R$. Then

(i) $\lambda$ is an eigenvalue of $D$ and the corresponding exponential is

(3.2) $x_\lambda = e_\lambda(z)$, where $e_\lambda = (I - \lambda R)^{-1}$, $z \in \ker D$;

whenever $e_\lambda = (I - \lambda R)^{-1}$ exists, is said to be an exponential operator;

(ii) the dimension of the eigenspace $X_\lambda$ corresponding to the eigenvalue $\lambda$ is equal to dimension of the space of constants, i.e. $\dim X_\lambda = \dim \ker D \neq 0$;

(iii) if $\lambda \neq 0$ then there exist non-trivial exponentials: $e_\lambda(z) \neq 0$.

(iv) exponentials are uniquely determined by their initial values, i.e. if $F$ is an initial operator for $D$ corresponding to $R$ then $F[e_\lambda(z)] = z$;

(v) if $R$ is a Volterra operator then every $\lambda \in \mathbb{F}$ is an eigenvalue of $D$, i.e. for every $\lambda \in \mathbb{F}$ there exist exponentials.

**Proof.** (i) By definition, $(I - \lambda R)e_\lambda(z) = (I - \lambda R)(I - \lambda R)^{-1}z = z$, where $z \in \ker D$. Thus $e_\lambda(z) = z + \lambda R e_\lambda(z)$, which implies $De_\lambda(z) = Dz + \lambda DR e_\lambda(z) = \lambda e_\lambda(z)$.  

10
(ii) Since by our assumptions, the operator $e_\lambda = I - \lambda R$ is invertible, \( \dim X_\lambda = \dim \{ e_\lambda(z) : z \in \ker D \} = \dim \{(I - \lambda R)^{-1}z : \ker D \} = \dim \ker D \neq 0. \)

(iii) If $\lambda \neq 0$ and $e_\lambda(z) = (I - \lambda R)^{-1}z = 0$ then $z = (I - \lambda R)e_\lambda(z) = 0$, This contradicts our assumption that $\ker D \neq \{0\}$.

(iv) By definitions and (i), we have $F e_\lambda(z) = (I-\lambda D)e_\lambda(z) = (I-\lambda R)e_\lambda(z) = z$.

(v) If $R \in V(X)$ then $v_\lambda R = F \{0\}$. Clearly, for $\lambda = 0$ the operator $I - \lambda R$ is also invertible. Hence, by (i), every scalar $\lambda$ is an eigenvalue of $D$. ■

Definition 3.2. Let $F = \mathbb{C}$. Suppose that $X$ is a linear space (over $\mathbb{C}$, $D \in R(X)$, $\ker D \neq \{0\}$ and $R \in \mathcal{R}_D \cap V(X)$. Then the operators

\begin{equation}
(3.3) \quad c_\lambda = \frac{1}{2} (e_{\lambda i} + e_{-\lambda i}), \quad s_\lambda = \frac{1}{2i} (e_{\lambda i} - e_{-\lambda i}) \quad (\lambda \in \mathbb{R})
\end{equation}

are said to be cosine and sine operators, respectively (or: trigonometric operators). Elements $c_\lambda(z)$, $s_\lambda(z)$, where $z \in \ker D$, are said to be cosine and sine elements, respectively (or: trigonometric elements).

Theorem 3.2. Suppose that all assumptions of Definition 3.2. are satisfied. Then

\begin{equation}
(3.4) \quad c_\lambda = (I + \lambda^2 R^2)^{-1}, \quad s_\lambda = \lambda R(I + \lambda^2 R^2)^{-1} \quad (\lambda \in \mathbb{R})
\end{equation}

\begin{equation}
(3.5) \quad Dc_\lambda = -\lambda s_\lambda, \quad Ds_\lambda = \lambda c_\lambda \quad (\lambda \in \mathbb{R})
\end{equation}

\begin{equation}
(3.6) \quad c_0(z) = z, \quad s_0(z) = 0, \quad Fs_\lambda(z) = 0 \text{ for } z \in \ker D, \quad \lambda \in \mathbb{R}.
\end{equation}

Moreover, whenever $z \in \ker D$, $\lambda \in \mathbb{R}$, the element $c_\lambda(z)$ is even with respect to $\lambda$ and the element $s_\lambda$ is odd with respect to $\lambda$.

Proof. By the first Formula of (3.4), for $\lambda \in \mathbb{R}$ we get

\[ c_\lambda = \frac{1}{2} [(I - \lambda i R)^{-1} + (I + \lambda i R)^{-1}] = \frac{1}{2} (I - \lambda i R)^{-1} (I + \lambda i R)^{-1} (I + \lambda i R + I - \lambda i R) = \]

\[ = \frac{1}{2} (I + \lambda^2 R^2)^{-1} 2I = (I + \lambda^2 R^2)^{-1}. \]

A similar proof for $s_\lambda$. By definitions, if $\lambda \in \mathbb{R}$, then

\[ Dc_\lambda = \frac{1}{2} D(e_{\lambda i} + e_{-\lambda i}) = \]

\[ = \frac{1}{2} (\lambda i e_{\lambda i} + \lambda i e_{-\lambda i}) = \frac{1}{2} \lambda i (e_{\lambda i} + e_{-\lambda i}) = -\frac{\lambda}{2i} (e_{\lambda i} + e_{-\lambda i}) = -\lambda s_\lambda. \]

11
Since $DR = I$, we have $Ds_\lambda = \lambda DR(I + \lambda^2 R^2)^{-1} = \lambda(I + \lambda^2 R^2)^{-1} = \lambda c_\lambda$.

Let $z \in \ker D$. Let $\lambda = 0$. Then $c_0(z) = z$, $s_0(z) = 0$. Since $FR = 0$, for every $\lambda \in R$ we have $Fs_\lambda(z) = \lambda FR(I + \lambda^2 R^2)^{-1} = 0$. Let $z \in \ker D$. Then

$$c_{-\lambda}(z) = [I + (-\lambda)^2 R^2]^{-1}(z) = (I + \lambda^2 R^2)^{-1}z = c_\lambda(z);$$

$$s_{-\lambda}(z) = -\lambda R[I + (-\lambda)^2 R^2]^{-1}(z) = -\lambda R(I + \lambda^2 R^2)^{-1}z = -s_\lambda(z).$$

Consider now trigonometric elements in algebras. It is easy to verify

**Proposition 3.6.** Suppose that $D \in A(X) \cap R(X)$, $\ker D \neq \{0\}$ and $R \in \mathcal{R}_D \cap V(X)$. Then

$$[c_\lambda(z)]^2 + [s_\lambda(z)]^2 = e_{\lambda i} (z) e_{-\lambda i} (z) \quad \text{for all } z \in \ker D, \; \lambda \in \mathbb{R}. \tag{3.6}$$

$$D[e_{\lambda i} (z) e_{-\lambda i} (z)] = c_D z + f_D (e_{\lambda i} (z), e_{-\lambda i z}) \quad \text{for all } z \in \ker D, \; \lambda \in \mathbb{R}. \tag{3.7}$$

**Corollary 3.2.** Suppose that $X$ is a Leibniz $D$-algebra $\ker D \neq \{0\}$ and $R \in \mathcal{R}_D \cap V(X)$. Then

$$D[e_{\lambda i} (z) e_{-\lambda i} (z)] = z \quad \text{for all } z \in \ker D, \; \lambda \in \mathbb{R}. \tag{3.8}$$

**Proof.** Since $X$ is a Leibniz $D$-algebra, we have $c_D = 1$ and $f_D = 0$. Hence Formulae (3.6) and (3.7) implies (3.8). \hfill \blacksquare

An immediate consequence of Corollary 3.2 is

**Corollary 3.3.** Suppose that $X$ is a Leibniz $D$-algebra $\ker D \neq \{0\}$ and $R \in \mathcal{R}_D \cap V(X)$. Then the Trigonometric Identity holds, i.e.

$$[c_\lambda(z)]^2 + [s_\lambda(z)]^2 = z \quad \text{for all } z \in \ker D, \; \lambda \in \mathbb{R}. \tag{3.9}$$

**Proposition 3.7.** (cf. PR[3]). Suppose that $X \in \mathbf{Lg}(D)$, $\lambda g = Re \in \text{dom } \Omega^{-1}$ for every $R \in \mathcal{R}_D$ and $\lambda \in \nu \mathbb{F} R$. Then there are $(L, E) \in G[\Omega]$ such that

$$E(\lambda g) = (I - \lambda R)^{-1}z = e_\lambda z \in \ker (D - \lambda I) \quad \text{for all } z \in \ker D.$$

**Proof.** Let $R \in \mathcal{R}_D$ be fixed. Elements of the form $u = e_\lambda z = (I - \lambda R)^{-1}z$ are well-defined for all $z \in \ker D$ and $(D - \lambda I) u = D(I - \lambda R)u = Dz = 0$. Moreover, $Du = \lambda u = u\lambda e = u\lambda DR e = uD(\lambda g)$, which implies that $\lambda g \in \text{dom } \Omega^{-1}$ and there are $(L, E) \in G[\Omega]$ such that $e_\lambda = u = E(\lambda g)$. \hfill \blacksquare
Definition 3.3. (cf. PR[3]). Suppose that $F = \mathbb{C}$, $X \in \text{Lg}(D)$ and $E_1 = \text{dom } \Omega^{-1}$ is symmetric, i.e. $-x \in E_1$ whenever $x \in E_1$. Let $(L, E) \in G[\Omega]$. Write

\begin{equation}
Cx = \frac{1}{2} [E(ix) + E(-ix)], \quad Sx = \frac{1}{2i} [E(ix) - E(-ix)] \quad \text{for } ix \in E_1.
\end{equation}

The mappings $C$ and $S$ are said to be cosine and sine mappings or trigonometric mappings. Elements $Cx$ and $Sx$ are said to be cosine and sine elements or trigonometric elements. \hfill \Box

Clearly, trigonometric mappings and elements have such properties as the classical cosine and sine functions. Namely, we have (proofs can be found in PR[3]):

Proposition 3.8. (cf. PR[3]). Suppose that all assumptions of Definition 3.3 are satisfied. Let $(L, E) \in G[\Omega]$. Then trigonometric mappings $C$ and $S$ are well-defined for all $ix \in E_1$ and have the following properties:

(i) The de Moivre formulae hold:

\[ E(ix) = Cx + iSx, \quad E(-ix) = Cx - iSx \quad \text{for } ix \in E_1. \]

In particular, if $X$ is a commutative Leibniz algebra then

\begin{equation}
(Cx + iSx)^n = C(nx) + iS(nx) \quad \text{for } ix \in E_1 \text{ and } n \in \mathbb{N};
\end{equation}

(ii) $C$ and $S$ are even and odd functions of their argument, respectively, i.e. $C(-x) = Cx$, $S(-x) = -Sx$ for $ix \in E_1$ and $C(0) = z \in \ker D \{0\}$, $S(0) = 0$. In particular, for all $ix \in E_1$

\begin{equation}
(Cx)^2 + (Sx)^2 = \frac{1}{2} [E(ix)E(-ix) + E(ix)E(ix)].
\end{equation}

(iii) The mappings $C'$, $S'$ defined as follows: $C'x = C(x+z)$, $S'x = S(x+z)$ for $ix \in E_0$, $z \in \ker D$ also satisfy assertions (i)-(ii).

(iv) For all $ix \in \text{dom } \Omega^{-1}$

\begin{equation}
(Cx)^2 + (Sx)^2 = E(ix)(E(-ix));
\end{equation}

\begin{equation}
DCx = -(Sx)Dx, \quad DSx = (Cx)Dx.
\end{equation}

Corollary 3.4. (cf. PR[3]). Suppose that all assumptions of Proposition 3.8 are satisfied and $X$ is a Leibniz $D$-algebra with unit $e$. Then the Trigonometric Identity holds, i.e.

\begin{equation}
(Cx)^2 + (Sx)^2 = e \quad \text{whenever } ix \in E_1.
\end{equation}
The following question arises: Do exist non-Leibniz algebras with the Trigonometric Identity (3.15)? The answer to this question is negative, i.e. non-Leibniz algebras with the Trigonometric Identity (3.15) do not exist (cf. PR[6]). In other words: The Leibniz condition is necessary and sufficient for the Trigonometric Identity to hold.

In order to apply trigonometric mappings, we shall make use of the following condition:

$$[C]_n \quad \mathbb{F} = \mathbb{C}, \; n \in \mathbb{N} \text{ is arbitrarily fixed, } X \in Lg(D^n), \; \Omega_1 = \Omega \text{ and } \Omega_n^{-1} \text{ is symmetric, i.e. } -x \in \text{dom } \Omega_n \text{ whenever } x \in \text{dom } \Omega_n.$$ 

Suppose now that Condition $[C]_2$ holds and $X \in L(D)$. Suppose that $\lambda \in \mathbb{C}, R \in R_D, g = Re$ and $\lambda i g \in \text{dom } \Omega_1$. If $(L_1, E_1) \in G[\Omega_1]$ and $(L_2, E_2) \in G[\Omega_2]$ then

$$\ker(D^2 + \lambda^2 I) = \{z_1 E(\lambda i g) + z_2 E(-\lambda i g) : z_1, z_2 \in \ker D\} = \{zC(\lambda g) + \tilde{z}S(\lambda g) : z, \tilde{z} \in \ker D\} = \{(z'' g + z') E_2(\frac{\lambda^2 g^2}{2}) : z', z'' \in \ker D\}.$$ 

The assumption that $\lambda i, -\lambda i \in v_C R$ ensures that $\lambda i g, -\lambda i g \in \text{dom } \Omega_1^{-1}$. In this case, $-\lambda^2 \in v_C R^2$.

4. Fourier-like problems for right invertible operators.

We will apply properties of trigonometric mappings and elements in order to find non-trivial solutions of some homogeneous initial and boundary value problems for difference of two right invertible operators (of the first and second order).

**Proposition 4.1.** Let $X \in L(D_i)$, ker $D_i \neq \{0\}$, $i = 1, 2$, ker $D_1 \cap \text{ker } D_2 = \mathbb{C} \mathbb{e} = \{\lambda e\}_{\lambda \in \mathbb{C}}$. Suppose that $x = uv$, where $u \in \ker D_2$, $v \in \ker D_1$. Then

$$\left( D_2 - D_1^2 \right)x = u(D_2 + \lambda^2 I)v - v(D_1^2 + \lambda^2 I)v \quad \text{for all } \lambda \in \mathbb{C} \{0\}.$$ 

**Proof.** By our assumptions, $D_2 u = 0$, $D_1 v = 0$ and both operators $D_1, D_2$ satisfy the Leibniz condition. This and Leibniz Formula (1.5) together imply that

$$D_2 - D_1^2)x = (D_2 - D_1^2)(uv) = D_2(uv) - D_1^2(uv) = uD_2 v + vD_2 u - uD_1^2 v - 2(D_1 u)(D_1 v) - vD_1^2 u = uD_2 v - vD_1^2 u = u(D_2 v + \lambda^2 v) - \lambda^2 uv - vD_1 u = u(D_2 + \lambda^2 I)v - v(D_1^2 + \lambda^2 I)u.$$ 

Proposition 4.1 immediately implies
Corollary 4.1. Let $X \in \mathbf{L}(D_i)$, ker $D_i \neq \{0\}$, $i = 1, 2$, ker $D_1 \cap$ ker $D_2 = \mathbb{C} e = \{\lambda e\}_{\lambda \in \mathbb{C}}$. Suppose that $x = uv$, where $u \in$ ker $D_2$, $v \in$ ker $D_1$. Then $(D_2 - D_1^2)x = 0$ if and only if $u(D_2 + \lambda^2 I)v - v(D_2^2 + \lambda^2 I)v = 0$ for all $\lambda \in \mathbb{C} \{0\}$.

Corollary 4.2. Let $X \in \mathbf{L}(D_i)$, ker $D_i \neq \{0\}$, $i = 1, 2$, ker $D_1 \cap$ ker $D_2 = \mathbb{C} e = \{\lambda e\}_{\lambda \in \mathbb{C}}$ and $x = uv$, where $u \in$ ker $D_2$, $v \in$ ker $D_1$. Then $(D_2 - D_1^2)x = 0$ if and only if $u \in I(\text{ker } D_2)$, $v \in I(\text{ker } D_1)$ and there is a $\lambda \in \mathbb{C} \{0\}$ such that

$$(4.2) \quad u^{-1}D_1^2 u = vD_2 v = -\lambda^2 e.$$ 

Proof. Equalities (4.2) hold if and only if $(D_1^2 + \lambda^2 I)u = 0$, $(D_2 + \lambda^2 I)v = 0$. This, and Corollary 4.1 together imply that $(D_2 - D_1^2)x = 0$ if and only if Equalities (4.2) hold.

Theorem 4.1. Suppose that $X \in \mathbf{L}(D_i)$, ker $D_i \neq \{0\}$, $i = 1, 2$, ker $D_1 \cap$ ker $D_2 = \mathbb{C} e = \{\lambda e\}_{\lambda \in \mathbb{C}}$ and almost averaging $F_0, F_1 \in \mathcal{F}_{D_1}$, $F_2 \in \mathcal{F}_{D_2}$ correspond to $R_0, R_1 \in \mathcal{R}_{D_1}$, $R_2 \in \mathcal{R}_{D_2}$, respectively. Suppose, moreover, that $x = uv$, where $u \in I(\text{ker } D_2)$, $v \in I(\text{ker } D_1)$ and there is a $\lambda \in v_C R_0$ such that Equalities (4.2) hold and a $u$ such that $F_1 u = 0$. Then the homogeneous initial value problem

$$(4.3) \quad (D_2 - D_1^2)x = 0,$$ 

with the homogeneous boundary condition

$$(4.4) \quad F_0 x = 0, \quad F_1 x = 0$$

and with the homogeneous initial condition

$$(4.5) \quad F_2 x = 0$$

is ill posed, since it has a non-trivial solution $x = uv$, where $v$ is an eigenvector of $R_2$ corresponding to the eigenvalue $-\lambda^2$.

Proof. By Corollary 4.3, elements $u, v$ are invertible by our assumption, hence they are not zero divisors and $x = uv$ is a non-trivial solution of the equation $(D_2 - D_1^2)x = 0$. Since $\lambda \in v_C R_0$, Equalities (4.2) implies that $v \in \text{ker } (D_2 + \lambda^2 I) = \text{ker } D_2(I + \lambda^2 I)R_2$, i.e. $v = -\lambda^{-2} R_2$, $u \in \text{ker } (D_1^2 + \lambda^2 I)$. Since $F_0 R_0 = 0$, we have $F_0 u = 0$. Since $u \in$ ker $D_2$, $v \in$ ker $D_1$ and initial operators $F_0, F_1, F_2$ are almost averaging, we find $F_0 x = F_0(uv) = v F_0 u = 0$, $F_1(uv) = v F_1 u = 0$, $F_2 x = F_2(uv) = u F_2 v = u(-\lambda^2 - 2) F_2 R_2 v = 0$ (for $F_2 R_2 = 0$).

Theorems 4.1 and 3.2 together imply

Corollary 4.3. Suppose that $X \in \mathbf{L}(D_i)$, ker $D_i \neq \{0\}$, $i = 1, 2$, ker $D_1 \cap$ ker $D_2 = \mathbb{C} e = \{\lambda e\}_{\lambda \in \mathbb{C}}$ and almost averaging $F_0, F_1 \in \mathcal{F}_{D_1}$, $F_2 \in \mathcal{F}_{D_2}$ correspond to $R_0, R_1 \in \mathcal{R}_{D_1}$, $R_2 \in \mathcal{R}_{D_2}$, respectively. Suppose, moreover, that $x = uv$, where $u \in I(\text{ker } D_2)$, $v \in I(\text{ker } D_1)$ and there are a $\lambda \in v_C R_0$ such that
Equalities (4.2) hold and a $z_0 \in \ker D_1$ such that $F_1 u = F_1 s_\lambda(z_0) = 0$. Then the initial value problem (4.3)-(4.5) is ill-posed and its non-trivial solution is $x = uv$, where $u = s_\lambda(z_0)$, $s_\lambda = \lambda R_0(\lambda^2 I + R_0^2)$, $F_1 u = 0$ for a $z_0 \in \ker D_1$, $v$ is an eigenvector of $R_2$ corresponding to the eigenvalue $-\lambda^2$.

**Theorem 4.3.** Suppose that $X \in L(D_1) \cap L(D_2)$, Condition $\mathbb{C}_2$ is satisfied with respect to the multifunction $\Omega^{(1)}_1$ induced by $D_1$, $(L^{(1)}_1, E^{(1)}_1) \in G[\Omega^{(1)}_1]$, $S^{(1)}$ is a sine mapping induced by $E^{(1)}_1$, $F_0, F_1, F_2$ are almost averaging initial operators corresponding to $R_0, R_1 \in R_{D_1}$, $R_2 \in R_{D_2}$, respectively, $g_1 = R_0 e$, there exist a $\lambda$ such that $i\lambda \in \mathbb{v}_C R_0$, $i\lambda g_1 \in \text{dom} (\Omega^{(1)}_1)^{-1}$, $S^{(1)}(\lambda g_1) \in \ker D_2$ and $F_1 S^{(1)}(\lambda g_1) = 0$. Then the initial value problem (4.3)-(4.5) is ill-posed and its non-trivial solution is $x = uv$, where $u = S^{(1)}(\lambda g_1) \in \ker D_2$, $v \in \ker D_1$ is an eigenvector of $R_2$ corresponding to the eigenvalue $-\lambda^2$, i.e. $0 \neq v \in \ker(I + \lambda^2 R_2)$.

Proof. Let $x = uv$. Then, by our assumptions, $(D_2 + \lambda^2 I)v = D_2(I + \lambda^2 R_2)v = 0$. Since both operators $D_1$ and $D_2$ satisfy the Leibniz condition and $u \in \ker D_2$, we can apply Corollary 4.1 in a similar way, as before. Since $F_0, F_1, F_2$ are almost averaging and $F_0 E^{(1)}_1(\pm i\lambda g_1) = e$ (cf. PR[3]), we find

$$
F_0 x = F_0(uv) = v F_0 u = v F_0 S^{(1)}(\lambda g_1) = v \frac{1}{2i} F_0 [E^{(1)}(i\lambda g_1) - E^{(1)}(-i\lambda g_1)] = \\
= \frac{1}{2i} v [F_0 E^{(1)}(i\lambda g_1) - F_0 E^{(1)}(-i\lambda g_1)] = \frac{1}{2i} v (e - e) = 0;
$$

$$
F_1 x = F_1(uv) = v F_1 u = v F_1 S^{(1)}(\lambda g_1) = 0;
$$

$$
F_2 x = F_2(uv) = u F_2 v = u F_2 (-\lambda^2 R_2 v) = -\lambda^2 u F_2 R_2 v = 0.
$$

\[\blacksquare\]

**Theorem 4.4.** Suppose that $X \in L(D_1) \cap L(D_2)$, Condition $\mathbb{C}_2$ is satisfied with respect to the multifunction $\Omega^{(1)}_1$ induced by $D_1$, $(L^{(1)}_1, E^{(1)}_1) \in G[\Omega^{(1)}_1]$, $C^{(1)}$ is a cosine mapping induced by $E^{(1)}_1$, $F_0, F_1, F_2$ are almost averaging initial operators corresponding to $R_0, R_1 \in R_{D_1}$, $R_2 \in R_{D_2}$, respectively, $g_1 = R_0 e$, there exist a $\lambda$ such that $i\lambda \in \mathbb{v}_C R_0$, $i\lambda g_1 \in \text{dom} (\Omega^{(1)}_1)^{-1}$, $C^{(1)}(\lambda g_1) \in \ker D_2$ and $F_0 C^{(1)}(\lambda g_1) = 0$. Then the initial value problem (4.3), (4.4),

$$
(4.6) \quad F_1 D x = 0
$$

is ill-posed and its non-trivial solution is $x = uv$, where $u = C^{(1)}(\lambda g_1) \in \ker D_2$, $v$ is an eigenvector of $R_2$ corresponding to the eigenvalue $-\lambda^2$, i.e. $0 \neq v \in \ker(I + \lambda^2 R_2)$.

Proof. Let $x = uv$. Then, by our assumptions, $u \in \ker D_2$, $D C^{(1)}(\lambda g_1) = -\lambda S^{(1)}(\lambda g_1)$. Thus, in a similar manner as in the proof of Theorem 4.1, we prove that $(D_2 - D_1^2)x = 0, F_0 x = 0, F_2 x = 0$. Condition $F_1 x = 0$ follows from the
fact that (as before) $F_1$ is almost averaging, hence $F_1 x = v F_1 u = v F_1 C^{(1)}(\lambda g_1) = \frac{1}{\lambda} v F_1 D S^{(1)}(\lambda) = 0$.

**Corollary 4.5.** Suppose that all assumptions of Theorem 4.2 are satisfied and $F_1 = F_0$, hence also $R_1 = R_0$. Then equation (4.3) has a non-trivial solution $x = uv$, where $u = C^{(1)}(\lambda g_1) \in \ker D_2$, $v$ is an eigenvector of $R_2$ corresponding to the eigenvalue $-\lambda^2$. This solution satisfies the homogeneous initial conditions

$$F_0 x = 0, \quad F_0 D x = 0, \quad F_2 x = 0.$$ 

Hence the problem (4.3),(4.7) is ill-posed.

**Theorem 4.3.** Suppose that $X \in L(D_1) \cap L(D_2)$, Condition [C] is satisfied with respect to the multifunction $\Omega^{(2)}_1$ induced by $D_2$, $(L^{(2)}_1, E^{(2)}_1) \in G[\Omega^{(2)}_1], S^{(2)}, C^{(2)}$ are sine and cosine mappings induced by $E^{(2)}_1$, $F_0, F_1, F_2$ are almost averaging initial operators corresponding to $R_0, R_1 \in \mathcal{R}_{D_1}, R_2 \in \mathcal{R}_{D_2}$, respectively, $g_2 = R_2 e$, there exist a $\lambda$ such that $i \lambda g_i \in v_0 R_2$, $-\lambda^2 g_2 \in \text{dom} (\Omega^{(2)}_1)^{-1}$, $z_0, z_1 \in \ker D_1$, $z_2 \in \ker D_2 \cap I(X)$ and

$$u = z_0 S^{(2)}(\lambda g_2) + z_1 C^{(2)}(\lambda g_2) \in I(X).$$

If $v = z_2 E^{(2)}_1 (-\lambda^2 g_2) \in \ker D_1$ then $x = uv \in I(X)$ is a non-trivial solution of Equation (4.3).

**Proof.** By the Leibniz condition, $v = z_2 E^{(2)}_1 (-\lambda^2 g_2) \in I(X)$. Then

$$(D_2 + \lambda^2 I)v = D_2 [z_2 E^{(2)}_1 (-\lambda^2 g_2) + \lambda^2 v] =$$

$$= -\lambda^2 z_2 E^{(2)}_1 (-\lambda g_2) D_2 R_2 e + \lambda^2 v = -\lambda^2 v + \lambda^2 v = 0.$$

By Formulae (3.16), $u \in \ker (D_2^2 + \lambda^2 I)$, in a similar manner, as in the proof of Corollary 4.1, we get

$$(D_1 - D_2^2)x = (D_1 - D_2^2)(uv) = u D_2 v - v D_1 u = u(-\lambda^2 v) - u(-\lambda^2 v) = 0.$$ 

**Theorem 4.4.** Suppose that $X \in L(D_1) \cap L(D_2)$, Condition [C] is satisfied with respect to the multifunctions $\Omega^{(i)}_1$ induced by $D_i$, $(L^{(i)}_1, E^{(i)}_1) \in G[\Omega^{(i)}_1], S^{(i)}$ are sine mappings induced by $E^{(i)}_1 (i = 1, 2)$, $F_0, F_1, F_2, F_3$ are almost averaging initial operators corresponding to $R_0, R_1 \in \mathcal{R}_{D_1}, R_2, R_3 \in \mathcal{R}_{D_2}$, respectively, $g_1 = R_0 e$, $g_2 = R_2 e$, there exist a $\lambda$ such that $i \lambda g_i \in v_0 R_0 \cap v_0 R_2$, $i \lambda g_i \in \text{dom} (\Omega^{(i)}_1)^{-1}$, $S^{(i)}(\lambda g_i) \in \ker D_j (j \neq i; i, j = 1, 2)$ and $F_1 S^{(1)}(\lambda g_1) = 0, F_3 S^{(2)}(\lambda g_2) = 0$. Then the equation

$$(D_1^2 - D_2^2)x = 0$$
has a non-trivial solution \( x = uv \), where \( u = S^{(1)}(\lambda g_1) \in \ker D_2 \), \( v = S^{(2)}(\lambda g_2) \in \ker D_1 \). This solution satisfies the homogeneous boundary conditions

\[
(4.10) \quad F_0 x = 0, \quad F_1 x = 0, \quad F_2 x = 0, \quad F_3 x = 0.
\]

Hence the problem (4.9)-(4.10) is ill-posed.

Proof. Let \( x = uv \). By definition, \( D_1^2 u = -\lambda^2 u, D_2^2 v = -\lambda^2 v \). Hence, in a similar way, as in the proof of Corollary 4.1, we find

\[
(D_1^2 - D_2^2)x = (D_1^2 - D_2^2)(uv) = vD_1^2 u - uD_2^2 v = -\lambda^2 uv + \lambda^2 uv = 0.
\]

By our assumptions, \( F_1 u = 0, F_3 v = 0 \) and \( u \in \ker D_2, v \in \ker D_1 \). Since \( F_1 \) and \( F_3 \) are almost averaging, we get \( F_1 x = F_1(uv) = vF_1 u = 0 \), \( F_3 x = F_3(uv) = uF_3 v = 0 \). As in the proof of Theorem 4.1, we find \( F_0 x = F_0(uv) = vF_0 u = vF_0 S^{(1)}(\lambda g_1) = 0 \). Similarly, \( F_2 x = F_2(uv) = uF_2 v = F_2 S^{(2)}(\lambda g_2) = 0 \).

**Theorem 4.5.** Suppose that \( X \in L(D_1)\cap L(D_2) \), Condition \([C]_2\) is satisfied with respect to the multifunction \( \Omega^{(1)} \) induced by \( D_1, (L^{(1)}, E^{(1)}) \in G[\Omega^{(1)}] \), \( S^{(1)} \) is a sine mapping induced by \( E^{(1)}_1 \), \( F_0, F_1, F_2, F_3 \) are almost averaging initial operators corresponding to \( R_0, R_1 \in \mathcal{R}_{D_1}, R_2, R_3 \in \mathcal{R}_{D_2} \), respectively, \( g_1 = R_0 e \), there exist a \( \lambda \) such that \( i\lambda \in \nu C R_0 \), \( i\lambda g_1 \in \text{dom } (\Omega^{(1)}{^{-1}}), u = S^{(1)}(\lambda g_1) \in \ker D_2, F_1 S^{(1)}(\lambda g_1) = 0 \) and \( 0 \neq v \in \ker D_1 \) is an eigenvector of the operator \( R_2 R_3 \) corresponding to the eigenvalue \( -\lambda^2 \). Then Equation (4.9) has a non-trivial solution \( x = uv \) which satisfies the homogeneous mixed boundary conditions

\[
(4.11) \quad F_0 x = 0, \quad F_1 x = 0, \quad F_2 x = 0, \quad F_3 D_2 x = 0.
\]

Hence the problem (4.9), (4.11) is ill-posed.

Proof. Following the proofs of Theorems 4.1 and 4.2, we prove that \( x = uv \) and \( F_0 x = F_1 x = 0 \). By our assumptions, \( D_2 u = 0, F_2 R_2 = 0, F_3 R_3 = 0 \), \( v = -\lambda^2 R_2 R_3 \), hence \( D_2 v = -\lambda^2 R_3 v \). Since \( F_2 \) and \( F_3 \) are almost averaging, we get

\[
F_2 x = F_2(uv) = uF_2 v = -\lambda^2 uF_2 R_2 R_3 v = 0,
\]

\[
F_3 D_2 x = F_3 D_2(uv) = F_3(uD_2 v + vD_2 u) = \quad F_3(uD_2 v) = uF_3 D_2 v = -\lambda^2 uF_3 R_3 v = 0.
\]

**Corollary 4.5.** Suppose that all assumptions of Theorem 4.5 are satisfied and \( F_3 = F_2 \), hence \( R_3 = R_2 \). Then Equation (4.9) has a non-trivial solution \( x = uv \), where \( 0 \neq v \in \ker D_1 \) is an eigenvector of the operator \( R_2^2 \) corresponding to the eigenvalue \( -\lambda^2 \). This solution satisfies the homogeneous boundary conditions

\[
(4.12) \quad F_0 x = 0, \quad F_1 x = 0
\]
and the homogeneous initial conditions

\begin{equation}
F_2 x = 0, \quad F_2 D_2 x = 0.
\end{equation}

Hence the problem (4.9), (4.12), (4.13) is ill-posed.

We should point out that we do not assume any right inverse under consideration to be a Volterra operator.

Under appropriate assumptions the Sylvester inertia law holds in algebras with logarithms (cf. PR[9]). We therefore can say that Equation (4.3) is parabolic-like and Equation (4.9) is hyperbolic-like whenever \( X \) is an algebra with logarithms. Indeed, these equations have forms \( (D_2 - D_1^2)x = 0, (D_2^2 - D_1^2)x = 0 \) of the classical canonic parabolic and hyperbolic equations, respectively (cf. Po[1]).

Clearly, a linear combination of solutions \( x_{\lambda_n} \) of any problem considered above corresponding to the eigenvalues \( \lambda_n \), is again a solution of that problem. Even more. Consider Equation (4.3). If we are given \( \lambda_j \in v_C R_2 \) such that \( \lambda_j \neq \lambda_k \) for \( j \neq k \) \((j, k = 1, ..., n; n \in \mathbb{N})\) then the corresponding eigenvectors \( v_{\lambda_j} \) \((j = 1, ..., n)\) are linearly independent and a linear combination

\[
x = \sum_{j=1}^{n} \alpha_j x_{\lambda_j} = \sum_{j=1}^{n} \alpha_j u_{\lambda_j} v_{\lambda_j},
\]

where \( \alpha_j \in \mathbb{C}, x_{\lambda_j} = u_{\lambda_j} v_{\lambda_j}, u_{\lambda_j} \in \ker (D_1^2 + \lambda_j^2) \(j = 1, ..., n\), is again a solution of Equation (4.3). A similar conclusion can be obtained for Equation (4.9).

Through this paper we have assumed several times that \( F_1 u = 0 \), where \( u \) was a sine element. However, under appropriate assumptions (\( X \) is a complete linear space over \( \mathbb{C} \), \( D \) is closed) in a complex extension of \( X \), exponentials, sine and cosine elements are \( 2\pi e \)-periodic:

\[
E[i(x + 2\pi e)] = E(ix), \quad C(x + 2\pi e) = Cx, \quad S(x + 2\pi e) = Sx,
\]

whenever these elements are well-defined (cf. PR[3], Chapter 9). If it is the case, we conclude that

\[
F_1 u = F_1 S(\lambda g) = F_1 S(\lambda g + 2\pi e) = F_1 S(\lambda g) = S(0) = 0,
\]

whenever \( g = \text{Re}, \ R \in \mathcal{R}_D, \lambda \in v_C R \).

ABSTRACT
FOURIER-LIKE METHODS FOR EQUATIONS WITH SEPARABLE VARIABLES

D. Przeworska-Rolewicz (Warszawa)

It is well known that a power of a right invertible operators is again right invertible, as well as a polynomial in a right invertible operator under appropriate assumptions. However, a linear combination of right invertible operators (in particular, their sum and/or difference) in general is not right invertible. It will be shown how to solve equations with linear combinations of right invertible operators in commutative algebras using properties of logarithmic and antilogarithmic mappings. The used method is, in a sense, a kind of the variables separation method. We shall obtain also an analogue of the classical Fourier method for partial differential equations.

Key words: algebraic analysis, commutative algebra with unit, Leibniz condition, logarithmic mapping, antilogarithmic mapping, right invertible operator, sine mapping, cosine mapping, initial value problem, boundary value problem, Fourier method
